

# Data Flow Analysis 1

Compiler Design

# Compiler Structure

- Source code parsed to produce abstract syntax tree.
- Abstract syntax tree transformed to *control flow graph*.
- *Data flow analysis* operates on the control flow graph (and other intermediate representations).

# Abstract Syntax Tree (AST)

- Programs are written in text
  - as sequences of characters
  - may be awkward to work with.
- First step: Convert to structured representation.
  - Use lexer (like lex) to recognize tokens
  - Use parser (like yacc) to group tokens structurally
    - often produce to produce AST

# Abstract Syntax Tree Example

`x := a + b;`

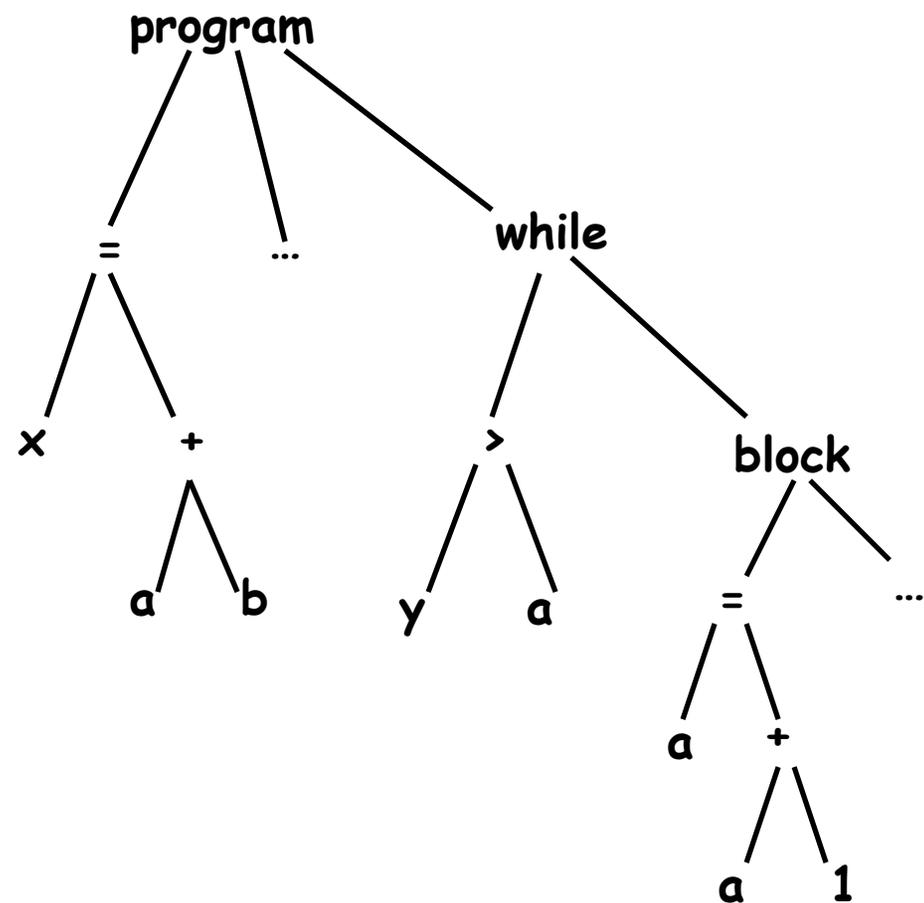

`y := a * b`

`While (y > a){`

`a := a + 1;`

`x := a + b`

`}`

# ASTs

- ASTs are abstract
  - don't contain all information in the program
    - e.g., spacing, comments, brackets, parenthesis.
- Any ambiguity has been resolved
  - e.g.,  $a + b + c$  produces the same AST as  $(a + b) + c$ .

# Disadvantages of ASTs

- ASTs have many similar forms
  - e.g., for while, repeat , until, etc
  - e.g., if, ?, switch
- Expressions in AST may be complex, nested

$(42 * y) + (z > 5 ? 12 * z : z + 20)$

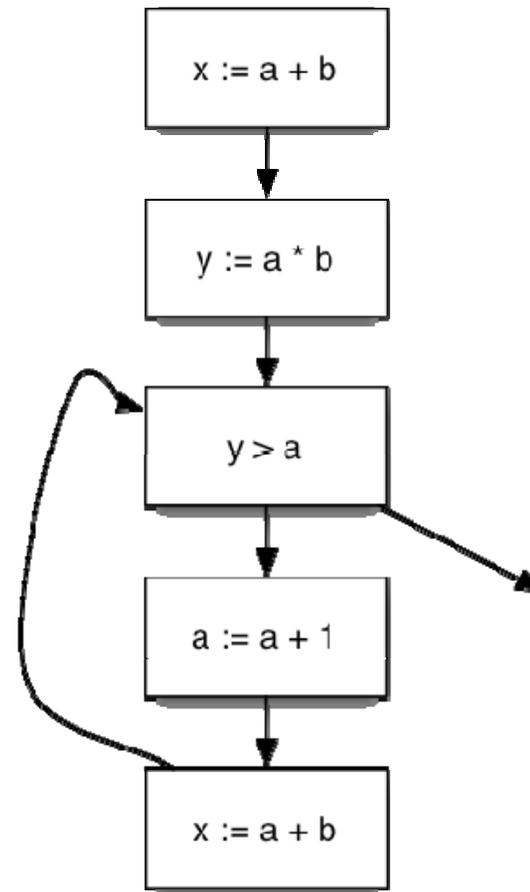

- Want simpler representation for analysis
  - ... at least for dataflow analysis.

# Control-Flow Graph (CFG)

- A directed graph where
  - Each node represents a statement
  - Edges represent control flow
- Statements may be
  - Assignments  $x = y \text{ op } z$  or  $x = \text{op } z$
  - Copy statements  $x = y$
  - Branches `goto L` or `if relop y goto L`
  - etc

# Control-flow Graph Example

```
x := a + b;  
y := a * b  
While (y > a){  
  a := a + 1;  
  x := a + b  
}
```

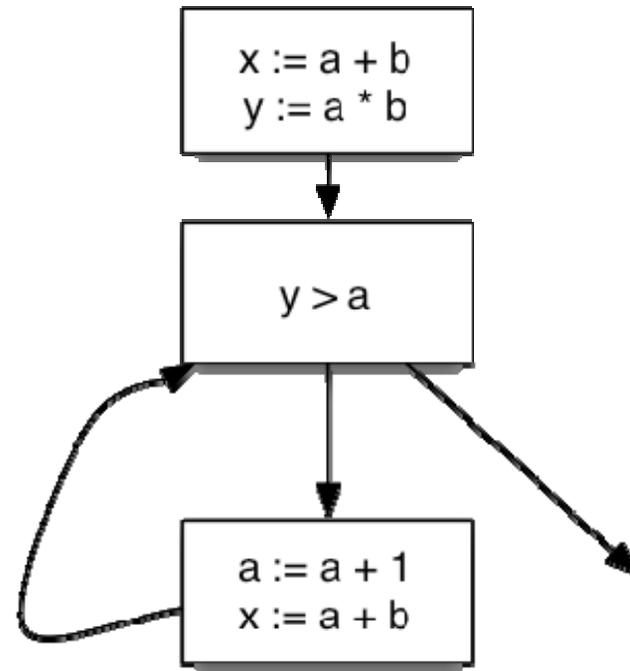

# Variations on CFGs

- Usually don't include declarations (e.g. `int x;`).
- May want a unique entry and exit point.
- May group statements into *basic blocks*.
  - A *basic block* is a sequence of instructions with no branches into or out of the block.

# Control-Flow Graph with Basic Blocks

```
X := a + b;  
Y := a * b  
While (y > a){  
    a := a + 1;  
    x := a + b  
}
```

- Can lead to more efficient implementations
- But more complicated to explain so...
  - We will use single-statement blocks in lecture

# CFG vs. AST

- CFGs are much simpler than ASTs
  - Fewer forms, less redundancy, only simple expressions
- But, ASTs are a more faithful representation
  - CFGs introduce temporaries
  - Lose block structure of program
- So for AST,
  - Easier to report error + other messages
  - Easier to explain to programmer
  - Easier to unparse to produce readable code

# Data Flow Analysis

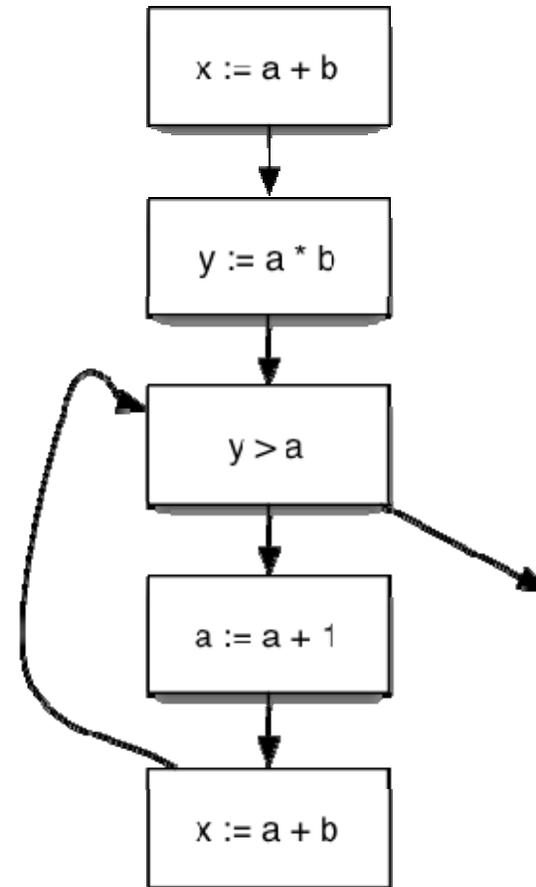

- A framework for proving facts about program
- Reasons about lots of little facts
- Little or no interaction between facts
  - Works best on properties about how program computes
- Based on all paths through program
  - including infeasible paths

# Available Expressions

- An expression  $e = x \text{ op } y$  is *available* at a program point  $p$ , if
  - on every path from the entry node of the graph to node  $p$ ,  $e$  is computed at least once, and
  - And there are no definitions of  $x$  or  $y$  since the most recent occurrence of  $e$  on the path
- Optimization
  - If an expression is available, it need not be recomputed
  - At least, if it is in a register somewhere

# Data Flow Facts

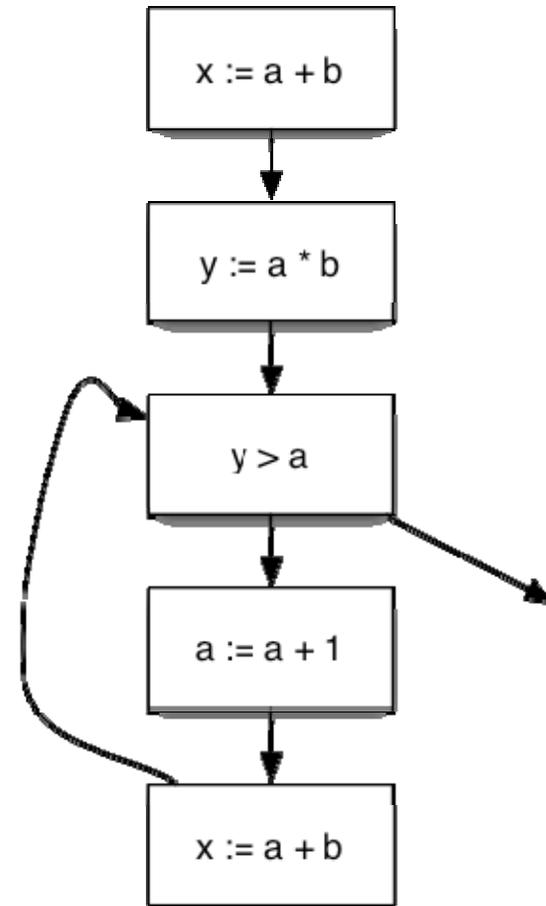

- Is expression  $e$  available?
- Facts:
  - $a + b$  is available
  - $a * b$  is available
  - $a + 1$  is available

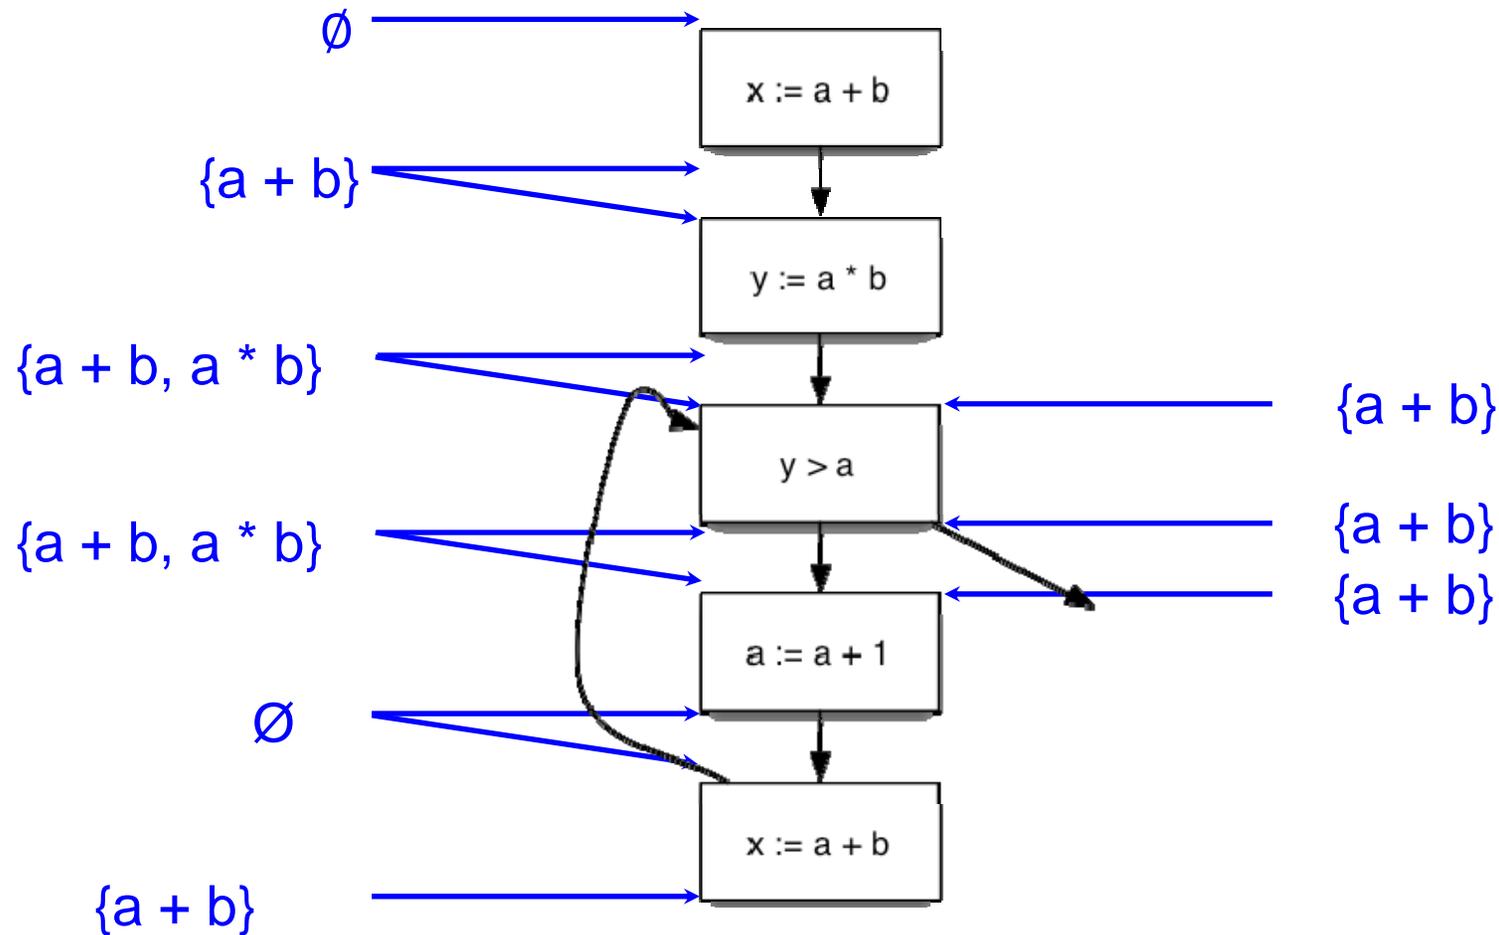

# Gen and Kill

What is the effect of each statement on the set of facts?

stmt	gen	kill
$x = a + b$	$a + b$	
$y = a * b$	$a * b$	
$a = a + 1$		$a + b$ $a * b$ $a + 1$

# Computing Available Expressions

# Terminology

- A *join point* is a program point where two branches meet
- Available expressions is a *forward, must problem*
  - *Forward* = Data Flow from in to out
  - *Must* = At joint point, property must hold on all paths that are joined.

# Data Flow Equations

- Let  $s$  be a statement
  - $\text{succ}(s) = \{\text{immediate successor statements of } s\}$
  - $\text{Pred}(s) = \{\text{immediate predecessor statements of } s\}$
  - $\text{In}(s)$  program point just before executing  $s$
  - $\text{Out}(s) = \text{program point just after executing } s$
- $\text{In}(s) = \bigcap_{s' \in \text{pred}(s)} \text{Out}(s')$
- $\text{Out}(s) = \text{Gen}(s) \wedge (\text{In}(s) - \text{Kill}(s))$ 
  - Note these are also called transfer functions

# Liveness Analysis

- A variable  $v$  is *live* at a program point  $p$  if
  - $v$  will be used on some execution path originating from  $p$  before  $v$  is overwritten
- Optimization
  - If a variable is not live, no need to keep it in a register
  - If a variable is dead at assignment, can eliminate assignment.

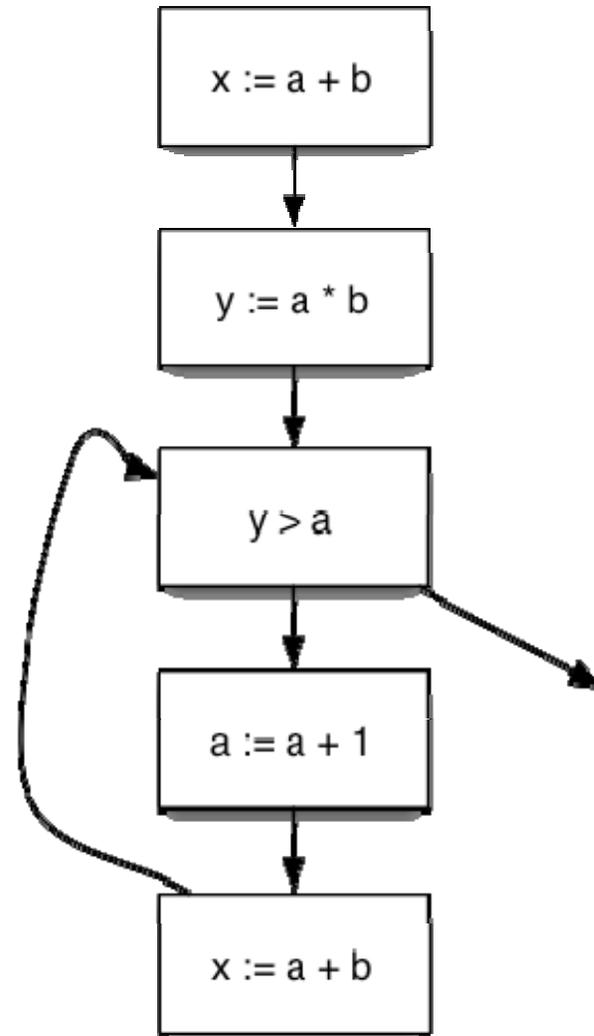

# Data Flow Equations

- Available expressions is a forward must analysis
  - Data flow propagate in same direction as CFG edges
  - Expression is available if available on all paths
- Liveness is a backward may problem
  - to know if variable is live, need to look at future uses
  - Variable is live if available on some path
- $In(s) = Gen(s) \wedge (Out(s) - Kill(s))$
- $Out(s) = \bigcup_{s' \in succ(s)} In(s')$

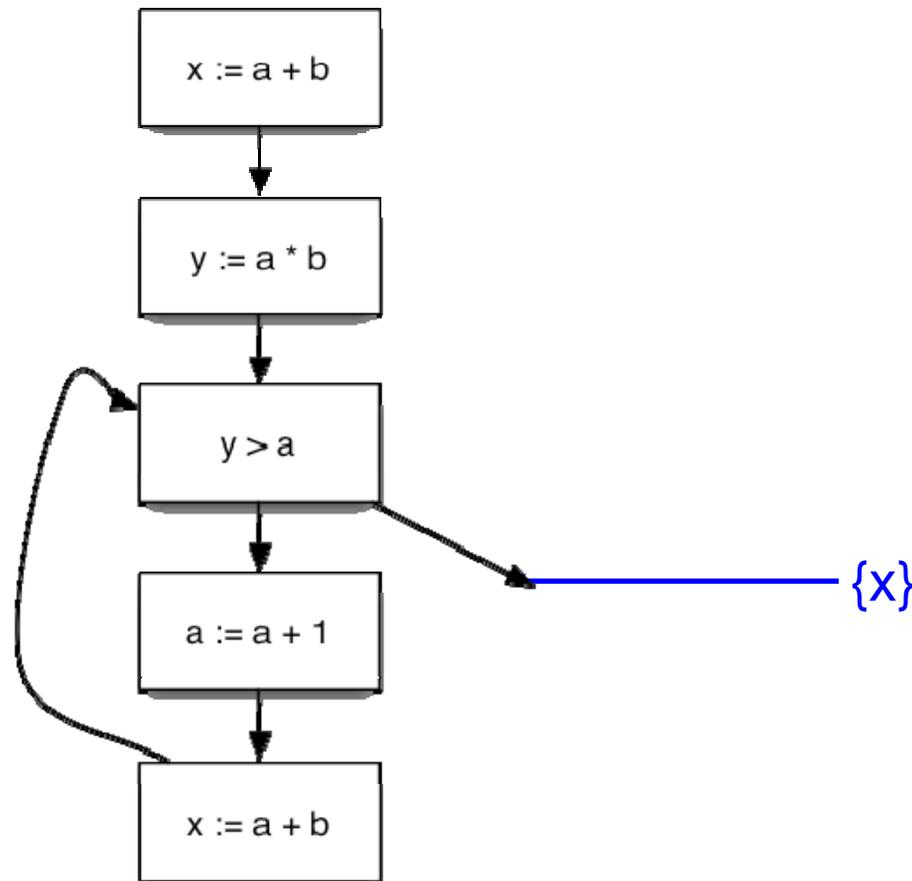

# Gen and Kill

What is the effect of each statement on the set of facts?

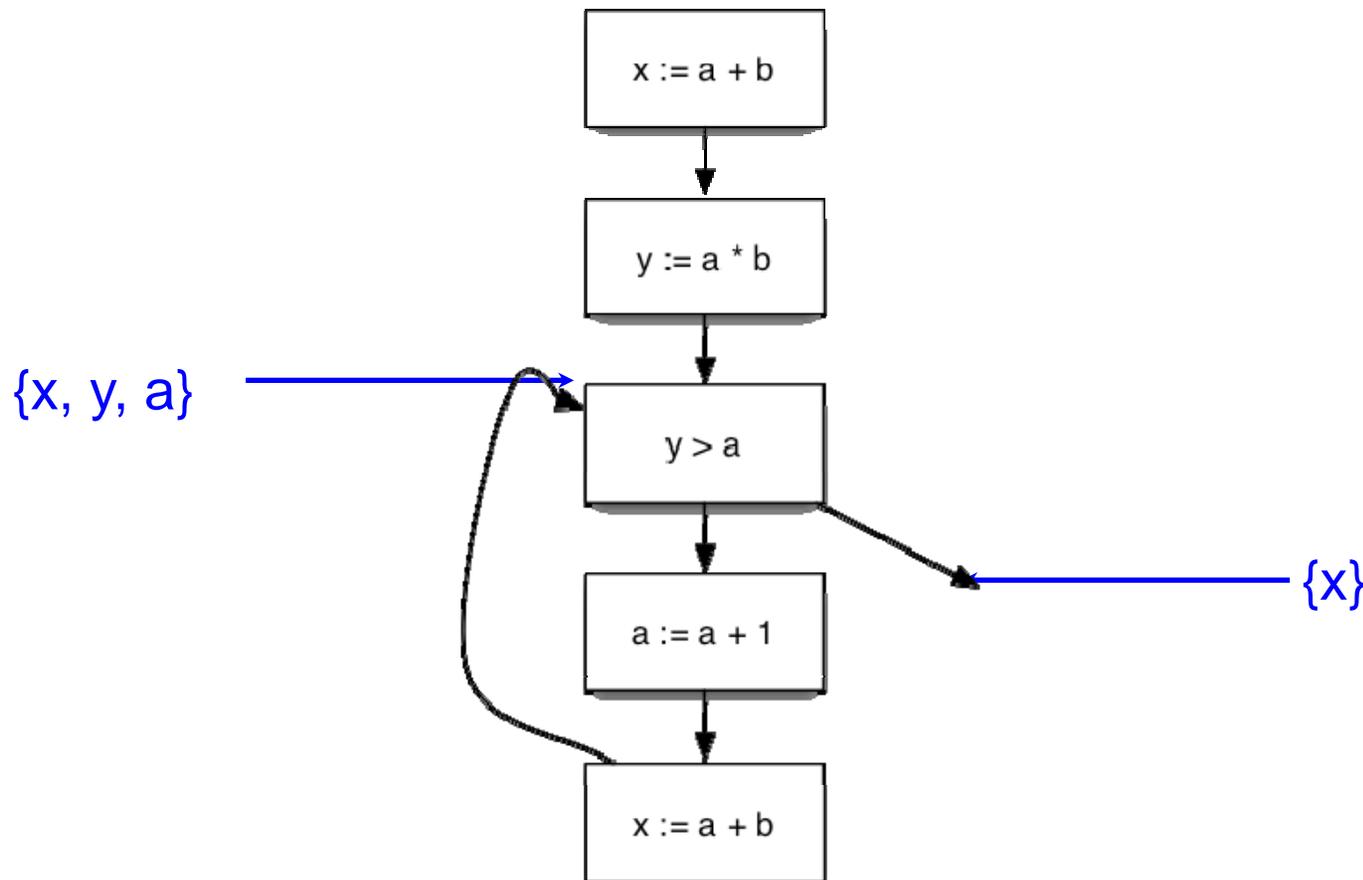

stmt	gen	kill
$x = a + b$	$a, b$	$x$
$y = a * b$	$a, b$	$y$
$y > a$	$a, y$	
$a = a + 1$	$a$	$a$

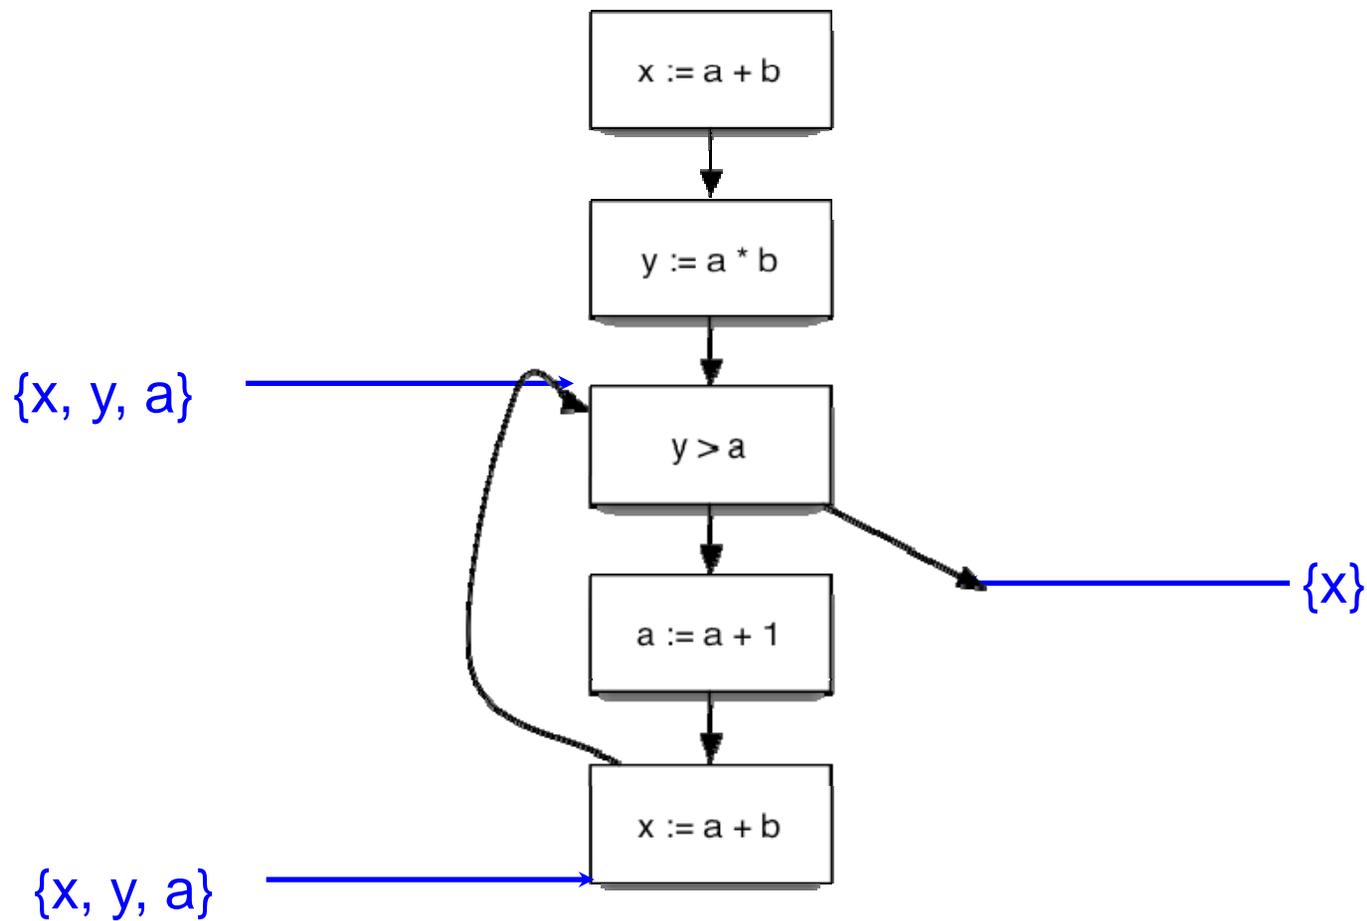

# Computing Live Variables

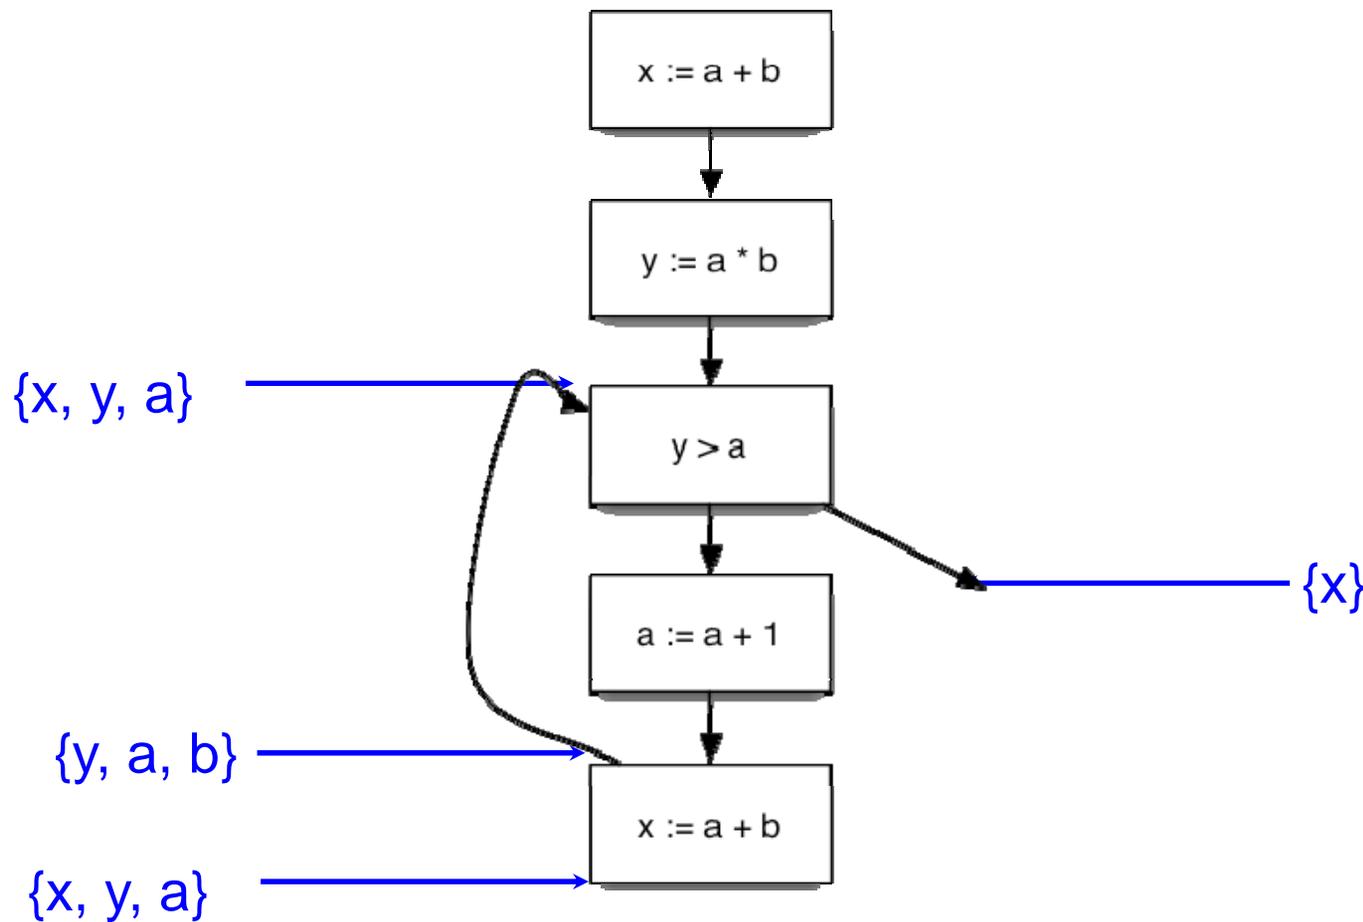

# Computing Live Variables

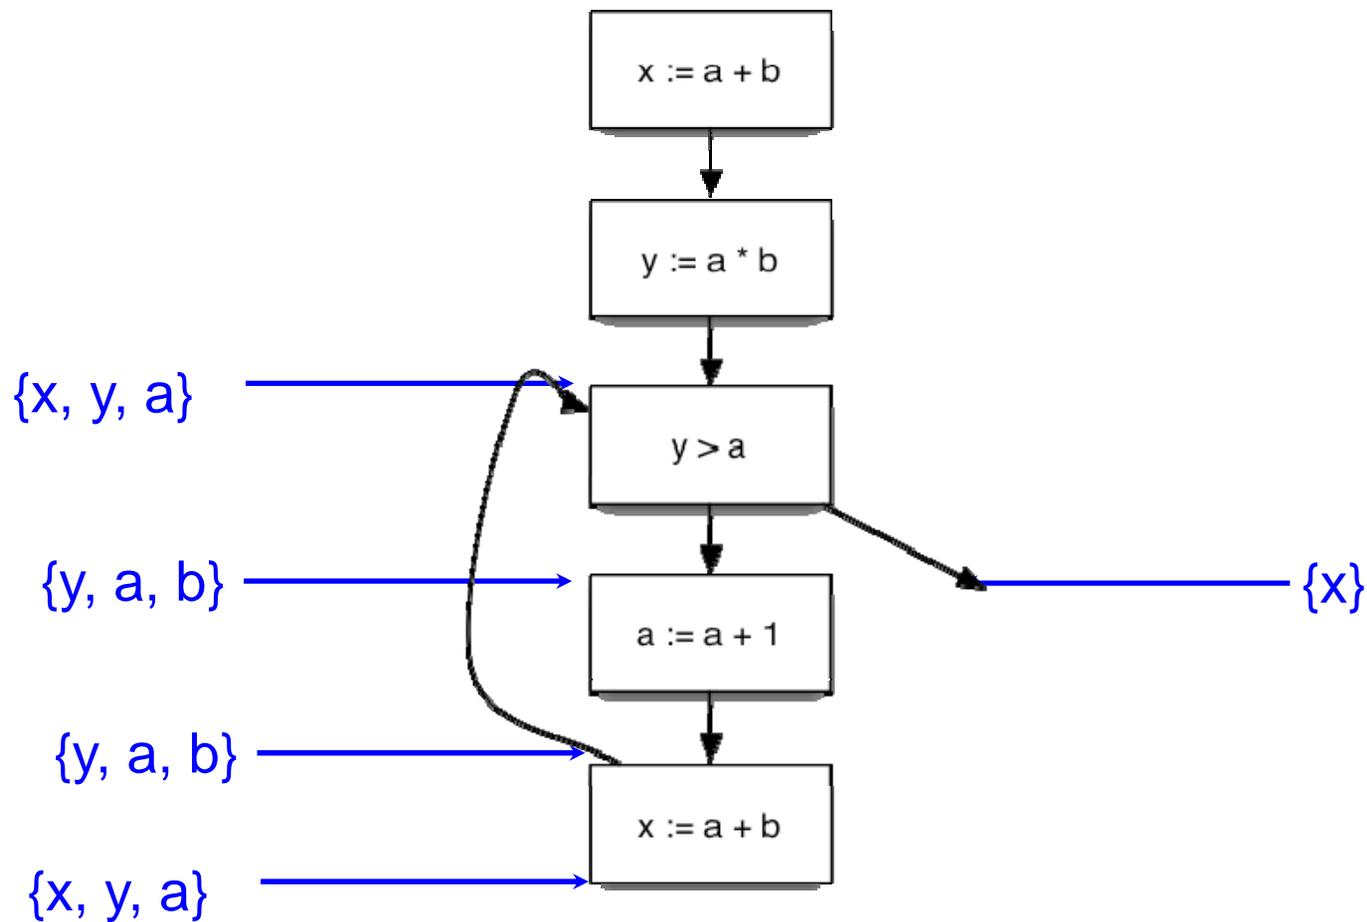

# Computing Live Variables

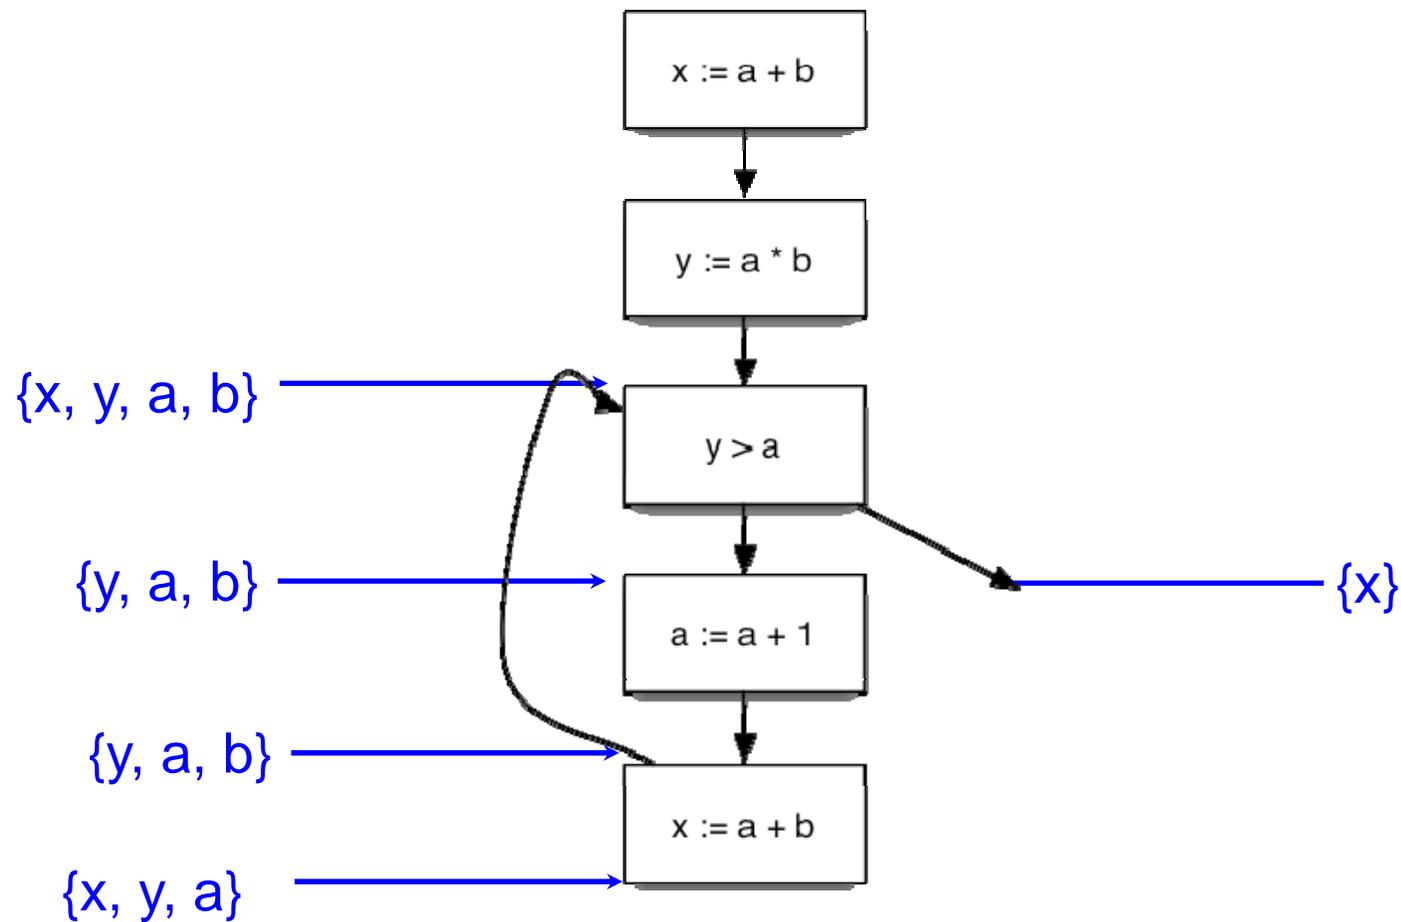

# Computing Live Variables

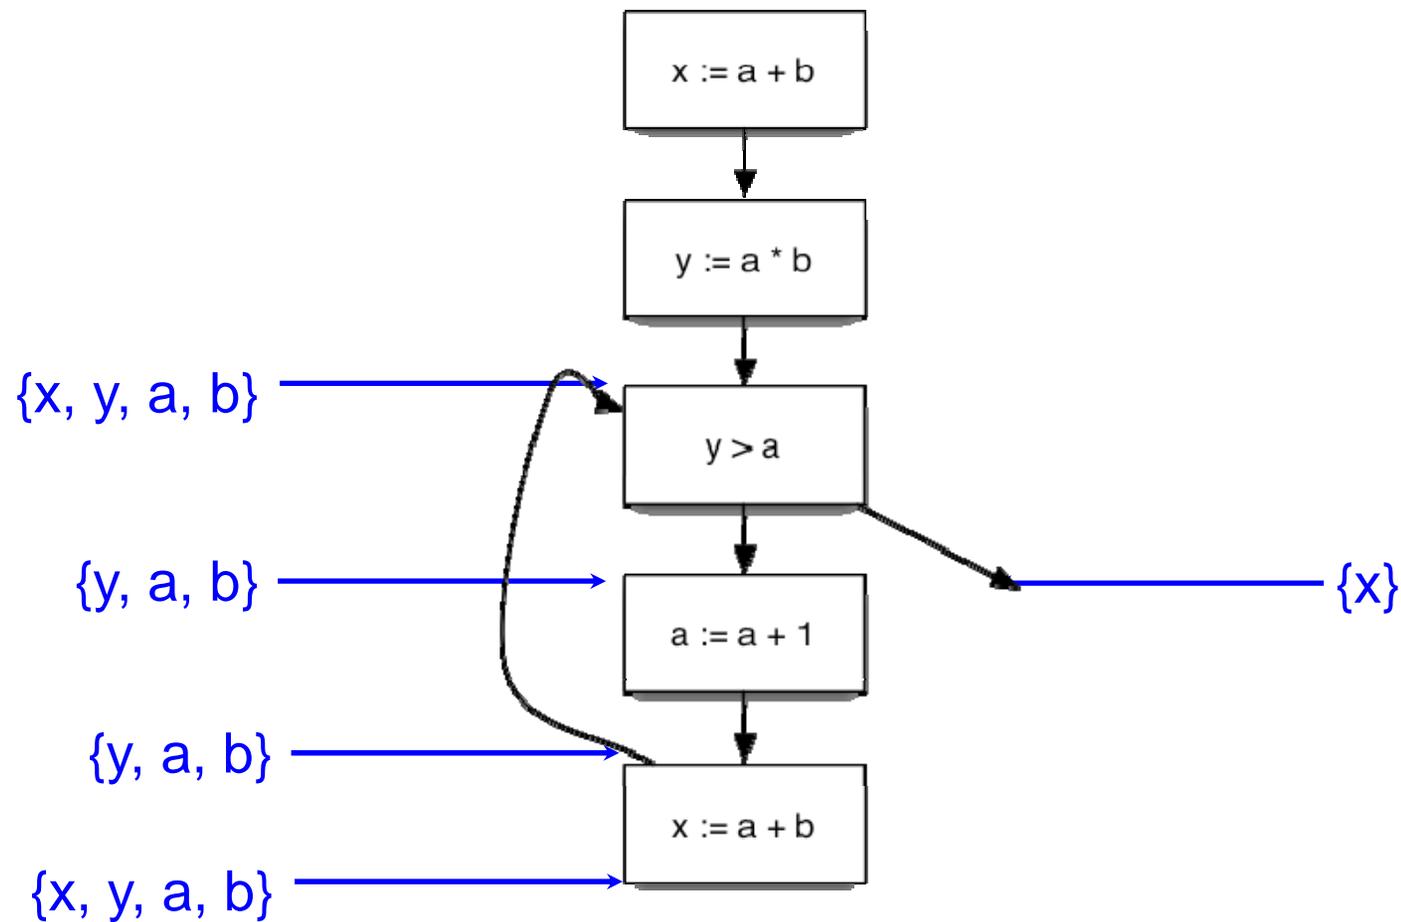

# Computing Live Variables

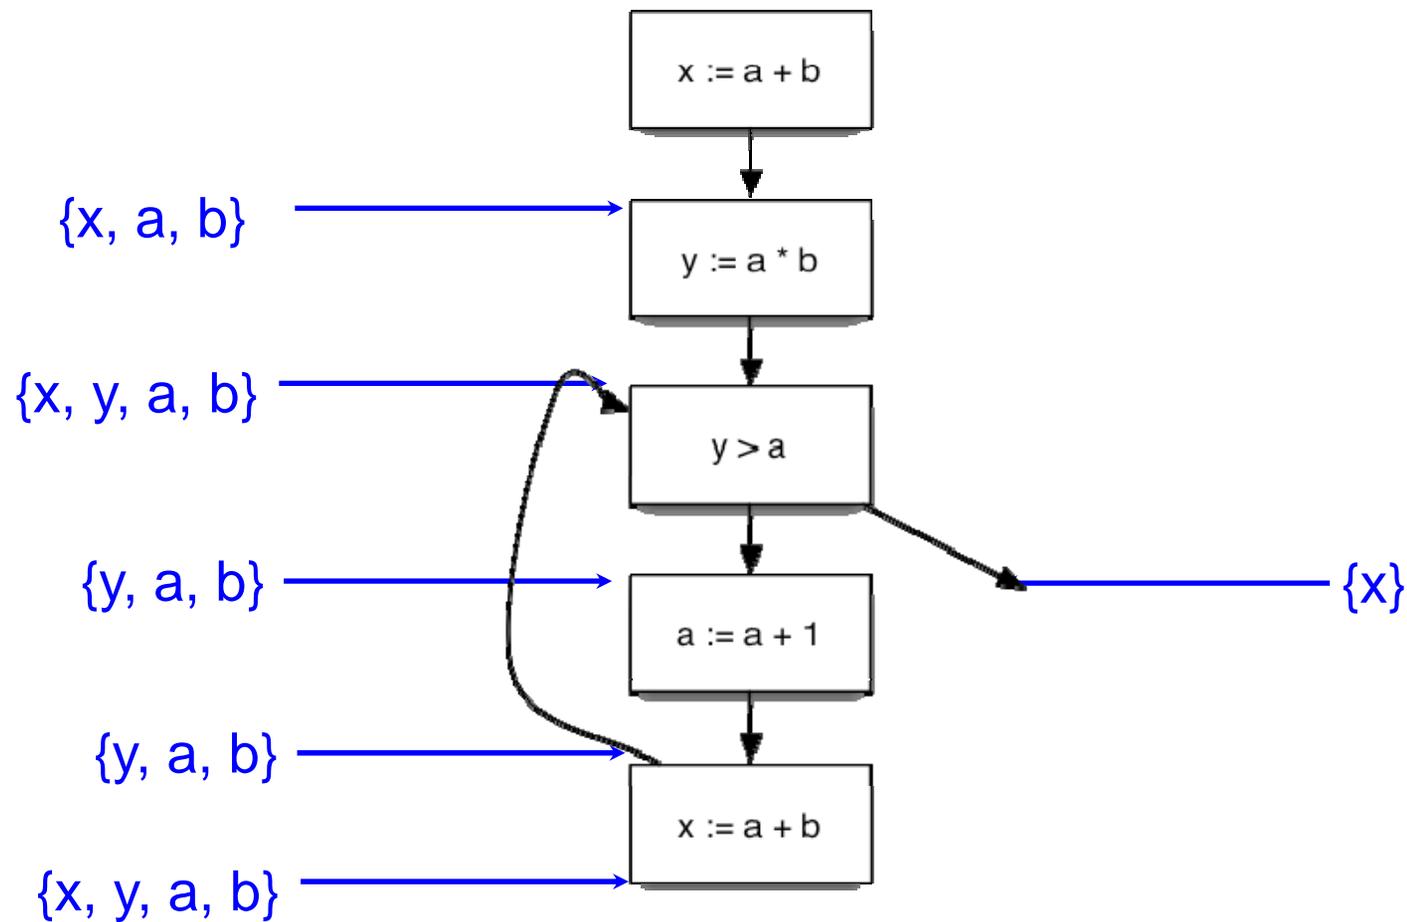

# Computing Live Variables

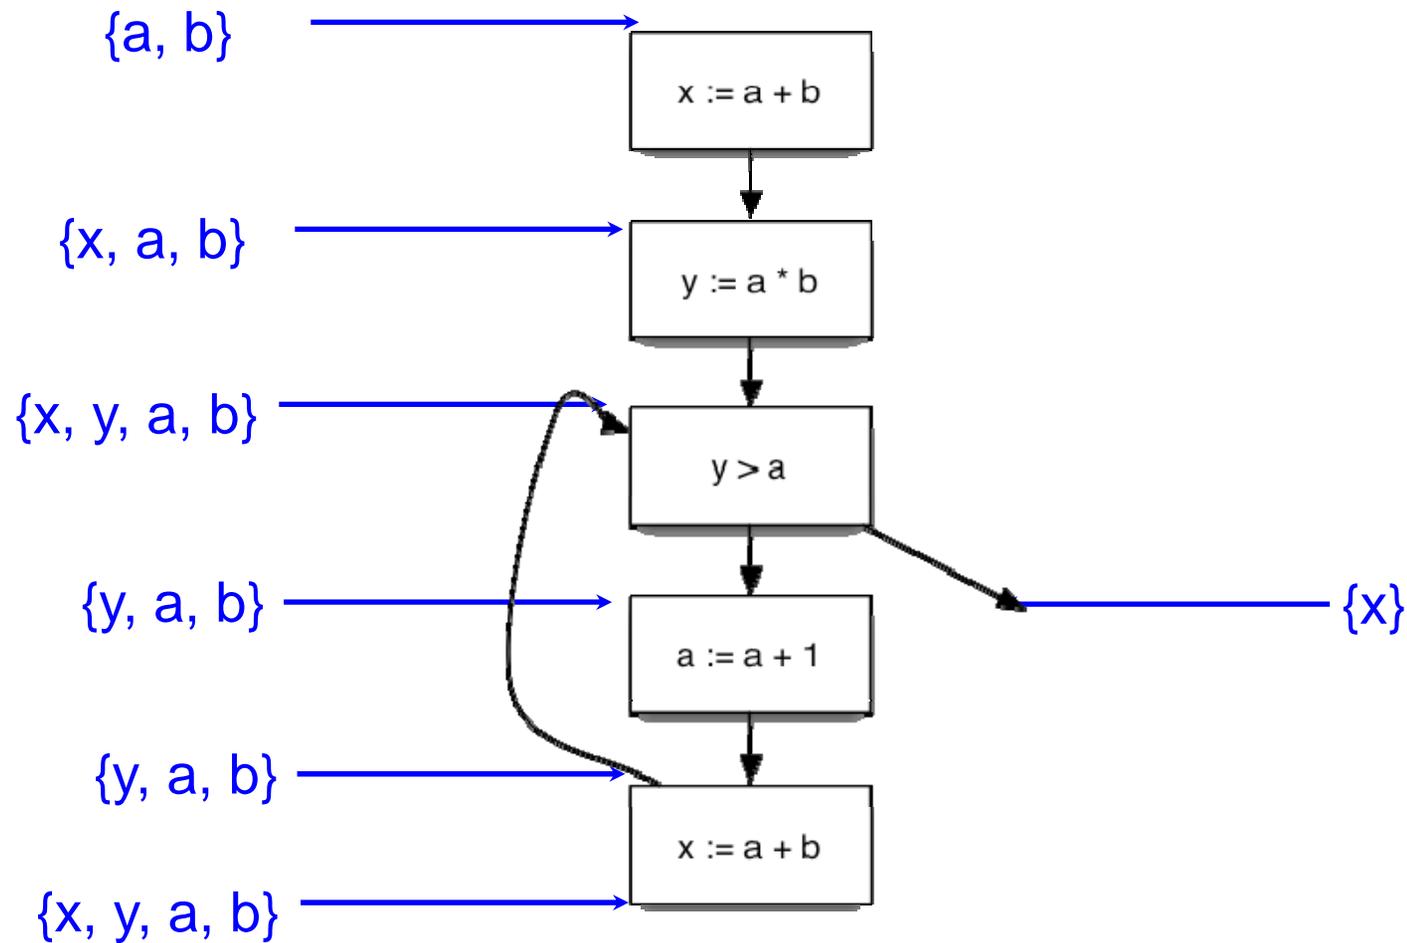

# Computing Live Variables

# Very Busy Expressions

- An expression  $e$  is *very busy at point  $p$*  if
  - On every path from  $p$ ,  $e$  is evaluated before the value of  $e$  is changed
- Optimization
  - Can hoist very busy expression computation
- What kind of problem?
  - Forward or backward? Backward
  - May or must? Must

# Code Hoisting

- Code hoisting finds expressions that are always evaluated following some point in a program, regardless of the execution path and moves them to the latest point beyond which they would always be evaluated.
- It is a transformation that almost always reduces the space occupied but that may affect its execution time positively or not at all.

# Reaching Definitions

- A *definition of a variable*  $v$  is an assignment to  $v$
- A definition of variable  $v$  *reaches* point  $p$  if
  - There is no intervening assignment to  $v$
- Also called *def-use* information
- What kind of problem?
  - Forward or backward? Forward
  - May or must? may

# Space of Data Flow Analyses

	<b>May</b>	<b>Must</b>
<b>Forward</b>	<b>Reaching definitions</b>	<b>Available expressions</b>
<b>Backward</b>	<b>Live Variables</b>	<b>Very busy expressions</b>

- Most data flow analyses can be classified this way
  - A few don't fit: bidirectional
- Lots of literature on data flow analysis

# Data Flow Facts and lattices

Typically, data flow facts form a lattice

Example, Available expressions

# Partial Orders

- A *partial order* is a pair  $(P, \preceq)$  such that
  - $\preceq \gg P \S P$
  - $\preceq$  is *reflexive*:  $x \preceq x$
  - $\preceq$  is *anti-symmetric*:  $x \preceq y$  and  $y \preceq x$  implies  $x = y$
  - $\preceq$  is *transitive*:  $x \preceq y$  and  $y \preceq z$  implies  $x \preceq z$

# Lattices

- A partial order is a lattice if  $\wedge$  and  $\vee$  are defined so that
  - $\wedge$  is the **meet** or **greatest lower bound** operation
    - $x \wedge y \leq x$  and  $x \wedge y \leq y$
    - If  $z \leq x$  and  $z \leq y$  then  $z \leq x \wedge y$
  - $\vee$  is the **join** or **least upper bound** operation
    - $x \leq x \vee y$  and  $y \leq x \vee y$
    - If  $x \leq z$  and  $y \leq z$ , then  $x \vee y \leq z$

# Lattices (cont.)

A finite partial order is a **lattice** if meet and join exist for every pair of elements

A lattice has unique elements **bot** and **top** such that

$$x \times B = B \quad x \vee B = x$$

$$x \times A = x \quad x \vee A = A$$

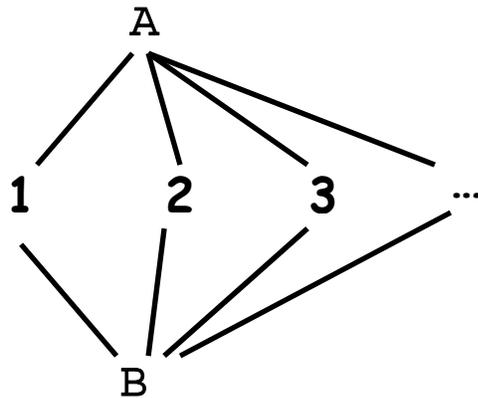

In a lattice

$$x \leq y \text{ iff } x \times y = x$$

$$x \leq y \text{ iff } x \vee y = y$$

# Useful Lattices

- $(2^S, \supseteq)$  forms a lattice for any set  $S$ .
  - $2^S$  is the powerset of  $S$  (set of all subsets)
- If  $(S, \%)$  is a lattice, so is  $(S, \dot{\%})$ 
  - i.e., lattices can be flipped
- The lattice for constant propagation

# Forward Must Data Flow Algorithm

$\text{Out}(s) = \text{Gen}(s)$  for all statements  $s$

$W = \{\text{all statements}\}$  (worklist)

Repeat

    Take  $s$  from  $W$

$\text{In}(s) = \bigcap_{s' \in \text{pred}(s)} \text{Out}(s')$

$\text{Temp} = \text{Gen}(s) \wedge (\text{In}(s) - \text{Kill}(s))$

    If ( $\text{temp} \neq \text{Out}(s)$ ) {

$\text{Out}(s) = \text{temp}$

$W = W \cup \text{succ}(s)$

    }

Until  $W = \emptyset$

# Monotonicity

- A function  $f$  on a partial order is **monotonic** if

$$x \preceq y \text{ implies } f(x) \preceq f(y)$$

- Easy to check that operations to compute In and Out are monotonic

- $\text{In}(s) = \bigcap_{s' \in \text{pred}(s)} \text{Out}(s')$
- $\text{Temp} = \text{Gen}(s) \wedge (\text{In}(s) - \text{Kill}(s))$

- Putting the two together

- $\text{Temp} = f_s \left( \bigcap_{s' \in \text{pred}(s)} \text{Out}(s') \right)$

# Termination

- We know algorithm terminates because
  - The lattice has finite height
  - The operations to compute In and Out are monotonic
  - On every iteration we remove a statement from the worklist and/or move down the lattice.
