# TOPICS COVERED

- Introduction to Groups
- Rings
- Abelian groups

# INTRODUCTION TO GROUP

- When we consider the behaviour of permutations under the composition operation we noticed certain underlying structures.
- Permutations are closed under this operation, they exhibit associativity, an identity element exists and an inverse exists for each permutation
- These properties define a general type of algebraic structure called a group.

# GROUPS

A group  $\langle G, \bullet \rangle$  or  $(G, \bullet)$  is a set  $G$  with binary operation  $\bullet$  which satisfies the following properties

1.  $\bullet$  is a closed operation i.e. if  $a \in G$  and  $b \in G$  then  $a \bullet b \in G$
2.  $\forall a, b, c \in G$   $a \bullet (b \bullet c) = (a \bullet b) \bullet c$  this is the associative law
3.  $G$  has an element  $e$ , called the identity, such that  $\forall a \in G$   $a \bullet e = e \bullet a = a$
4.  $\forall a \in G$  there corresponds an element  $a^{-1} \in G$  such that  $a \bullet a^{-1} = a^{-1} \bullet a = e$

**Examples:** (1) The set of all permutations of a set  $A$  onto itself is group (called the *symmetric group*  $S_n$  for  $n$  elements).

(2) The set consisting of all  $(n \times n)$  matrices that have inverses is a group under ordinary matrix multiplication ( it is called  $GL(n)$  ).

To show that an algebraic system is a group we must show that it satisfies all the axioms of a group.

Question: Let  $\langle A, \wedge, \vee, \bar{\phantom{x}} \rangle$  be a Boolean algebra so that  $A$  is a set of propositional elements,  $\vee$  is like 'or',  $\wedge$  is like 'and' and  $\bar{\phantom{x}}$  is like 'not'. Show that  $\langle A, \oplus \rangle$  is an abelian group where

$$\forall a, b \in A \quad a \oplus b = (a \wedge \bar{b}) \vee (\bar{a} \wedge b)$$

Answer:

(1) Associative since  $(a \oplus b) \oplus c = a \oplus (b \oplus c)$   
prove this ?

(2) Has an identity element 0 (false) since

$$\forall a \quad a \oplus 0 = (a \wedge \bar{0}) \vee (\bar{a} \wedge 0) = (a \wedge 1) \vee 0$$

$$= a \vee 0 = a$$

(3) Each element is its own inverse

$$a \oplus a = (a \wedge \bar{a}) \vee (\bar{a} \wedge a) = 0 \vee 0 = 0$$

(4) The operation commutes  $a \oplus b = b \oplus a$   
prove this ?

# GROUP OF SYMMETRIES OF A TRIANGLE

Consider the triangle

We can perform the following transformations on the triangle

$1$  = identity mapping from the plane to itself

$p$  = rotation anticlockwise about  $O$  through  $120$  degrees

$q$  = rotation clockwise about  $O$  through  $120$  degrees

$a$  = reflection in  $l$

$b$  = reflection in  $m$

$c$  = reflection in  $n$

Let  $x \bullet y$  denote transformation  $y$  followed by transformation  $x$  for  $x$  and  $y$  in  $\{1, p, q, a, b, c\}$

So for example  $p \bullet a = c$

$\bullet$	1	p	q	a	b	c
1	1	p	q	a	b	c
p	p	q	1	c	a	b
q	q	1	p	b	c	a
a	a	b	c	1	p	q
b	b	c	a	q	1	p
c	c	a	b	p	q	1

Notice the table is not symmetric

# ABELIAN GROUPS

If  $\langle G, \bullet \rangle$  is a group and  $\bullet$  is also commutative then  $\langle G, \bullet \rangle$  is referred to as an *Abelian group* (the name is taken from the 19'th century mathematician N.H. Abel)

- is commutative means that

$$\forall a, b \in G, a \bullet b = b \bullet a$$

**Examples:**  $\langle \mathbb{R}, + \rangle, \langle \mathbb{Z}, + \rangle$  and  $\langle \mathbb{R} - \{0\}, \times \rangle$  are abelian groups.

Why is  $\langle \mathbb{R}, \times \rangle$  not a group at all?

$$\begin{aligned} \text{If } \forall a, b \in \mathbb{Z} \ a \oplus b &= a + b \text{ if } a + b < n \\ &= a + b - n \text{ if } a + b \geq n \end{aligned}$$

then  $\langle \mathbb{Z}, \oplus \rangle$  is an abelian group and is usually referred to as the group of *integers modulo n*

# RING

An algebraic system  $\langle A, \oplus, \bullet \rangle$  is called a *ring* if the following conditions are satisfied:

- (1)  $\langle A, \oplus \rangle$  is an Abelian group
- (2)  $\langle A, \bullet \rangle$  is a semigroup
- (3) The operation  $\bullet$  is distributive over the operation  $\oplus$

Example:  $\langle \mathbb{Z}, +, \times \rangle$  is a ring since

$\langle \mathbb{Z}, + \rangle$  is an Abelian group

$\langle \mathbb{Z}, \times \rangle$  is a semigroup

$\times$  distributes over  $+$

A *commutative ring* is a ring in which  $\bullet$  is commutative

A *ring with unity* contains an element  $1$  such that  $\forall x \in A \ x \bullet 1 = 1 \bullet x = x$  where  $1 \neq 0$  ( $0$  is the identity of  $\langle A, \oplus \rangle$  )

Example: the ring of  $2 \times 2$  matrices under matrix addition and multiplication is a ring with unity.

The element  $1 = I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

# SEMIGROUP

An Abelian group is a strengthening of the notion of group (i.e. requires more axioms to be satisfied)

We might also look at those algebraic structures corresponding to a weakening of the group axioms

$\langle A, \bullet \rangle$  is a semigroup if the following conditions are satisfied:

1.  $\bullet$  is a closed operation i.e. if  $a \in A$  and  $b \in G$  then  $a \bullet b \in A$
2.  $\bullet$  is associative

**Example:** The set of positive even integers  $\{2,4,6,\dots\}$  under the operation of ordinary addition since

- The sum of two even numbers is an even number
- $+$  is associative

The reals or integers are not semigroups under - why?

# APPLICATION & FUTURE SCOPE

- Coding Theory
- Cryptography
