

## Introduction to Engineering Materials

# Imperfections in Solids

### ISSUES TO ADDRESS...

- What types of defects arise in solids?
- Can the number and type of defects be varied and controlled?
- How do defects affect materials' properties?
- Are defects undesirable?

1

## Defects by Dimension

- Zero-dimensional (point defects): vacancies, interstitial atoms, substitutional atoms.
- One-dimensional (linear defects): Mistakes in stacking planes of atoms. A plane of atoms sends in a line. Dislocations.
- Two-dimensional (planar or rare defects): surfaces and grain boundaries.
- Three-dimensional: Second phases.

2

# Why do we care about defects?

Many properties may be altered by defects/impurities.

e.g.

1) Mechanical properties: Metal alloys for improving strength.

2) Electrical properties:

- Defects and impurities can reduce metal conductivity.
- Doping in semiconductors to control of conductivity.

3) Optical properties:

- Wavelengths of light being absorbed and/or emitted by materials can be altered with imperfections.

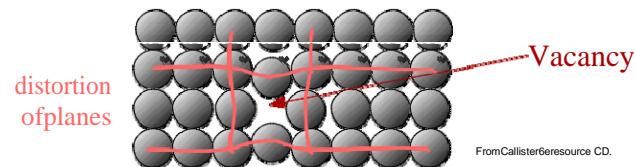

Mn-doped ZnSe quantum dots.

and many more examples....

## Point Defects

1. **Vacancies**: missing atoms from lattice sites.

Vacancies will also cause missing bonds (costs energy to create vacancies).

Why should vacancies form?

Consider the energy required to create a vacancy.

$$Q_v = \text{Activation energy to create vacancy}$$

Where does the energy to overcome  $Q_v$  come from?

**Thermal Energy!**

$k$  = Boltzmann constant

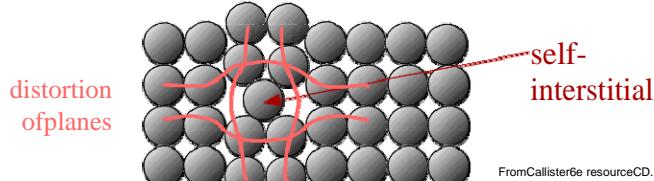

$$N_v = N \exp\left(-\frac{Q_v}{kT}\right)$$

No. of vacancies      Total No. of lattice sites       **$N_v$  depends on temperature!**

Typically:  $\frac{N_v}{N} \sim 10^{-4}$

## Point Defects

2. **Self-interstitial:** an extra atom (of the same type as the lattice atoms) placed in between lattice sites.

From Callister 6e resource CD.

For equilibrium number of self-interstitials: treats similarly as vacancies.

$$N_s = N \exp \left( -\frac{Q_s}{kT} \right)$$

Self-interstitials are usually not as highly probable as vacancies. **WHY?**

Typically, interstitial sites are much smaller than lattice atoms.

Self-interstitials would likely introduce significantly larger distortions!

i.e.  $Q_s \gg Q_v$

5

## Point defects: example problem

Calculate the equilibrium number of vacancies for a cubic centimeter of copper at 1000°C.

$$Q_v = 0.9 \text{ eV/atom}$$

$$A = 63.5 \text{ g/mol}$$

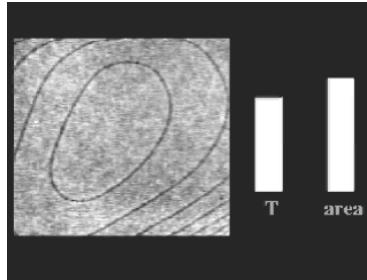

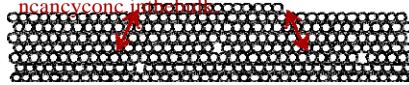

$$d = 8.4 \text{ g/cm}^3$$

$$k = 1.38 \times 10^{-23} \text{ J/K} = 8.62 \times 10^{-5} \text{ eV/K}$$

6

## Observing equilibrium vacancy concentration

- Low energy electron microscope view of a(110) surface of NiAl.
- Increasing T causes surface island of atoms to grow.
- Why? The equil. vacancy conc. increases via atom motion from the crystal to the surface, where they join the island. Island grows/shrinks to maintain equil. vacancy conc. in bulk.

Reprinted with permission from [Nature](#)

7

## Impurities in solids

1. In the limit of small number of impurities: consider as point defects.
2. When there is a large amount: consider as **solution**.  
Many familiar materials are highly impure (e.g. metal alloys).

### **Solid solutions**

Homogeneous distribution of impurities (similar to liquid solutions) with the crystal structure of the host material maintained.

**Solvent**: element or compound that is most abundant (host atoms).

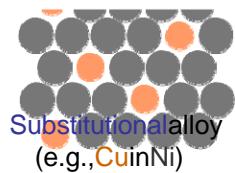

**Solute**: element or compound present in minor concentration (impurity).

8

## Point defects in alloys

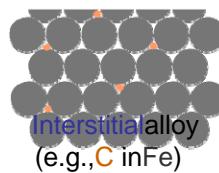

Two outcomes if impurity(B) added to host (A):

- Solid solution of B in A (i.e., random dist. of point defects)

Substitutional alloy  
(e.g., Cu in Ni)

OR

Interstitial alloy  
(e.g., C in Fe)

- Solid solution of B in A plus particles of a new phase (usually for a larger amount of B)

Second phase particle  
--different composition  
--often different structure.

9

## Solubility for solid solutions

A. Solubility of substitutional solution will depend on:

1. **Atomic size factor**: typically, atomic radius difference < 15%. Too large or too small impurity atom will cause too much lattice distortion!
2. **Crystal structure**: For appreciable solubility, host and impurity atoms should have the same crystal structure.
3. **Electronegativity**: Too large electronegativity difference will lead to intermetallic compounds rather than solutions.
4. **Valence**: Same valence is preferred for high solubility.

10

**Example**

**Is solid-solution favorable, or not?**

• **Si-Ge Alloys**

Rule1:  $r_{\text{Si}}=0.117\text{ nm}$  and  $r_{\text{Ge}}=0.122\text{ nm}$ .

$\Delta R\% = 4\%$

**favorable ✓**

Rule2: Si and Ge have the diamond crystal structure. **favorable ✓**

Rule3:  $E_{\text{Si}}=1.90$  and  $E_{\text{Ge}}=2.01$ . Thus,  $\Delta E\% = 5.8\%$  **favorable ✓**

Rule4: Valency of Si and Ge are both 4. **favorable ✓**

**Expect Si and Ge to form S.S. over wide decomposition range.**

In fact, solid solution forms over entire composition at high temperature.

11

**Example**

**Is solid-solution favorable, or not?**

• **Cu-Ag Alloys**

Rule1:  $r_{\text{Cu}}=0.128\text{ nm}$  and  $r_{\text{Ag}}=0.144\text{ nm}$ .

$\Delta R\% = 9.4\%$

**favorable ✓**

Rule2: Ag and Cu have the FCC crystal structure. **favorable ✓**

Rule3:  $E_{\text{Cu}}=1.90$  and  $E_{\text{Ni}}=1.80$ . Thus,  $\Delta E\% = -5.2\%$

**favorable ✓**

Rule4: Valency of Cu is +2 and Ag is +1. **NOT favorable**

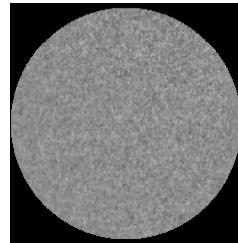

**Expect Ag and Cu to have limited solubility.**

In fact, the Cu-Ag phase diagram (T vs. c) shows that a solubility of only 18% Ag can be achieved at high T in the Cu-rich alloys.

12

## Alloying a surface

- Low energy electron microscope view of a (111) surface of Cu.
- Sn islands move along the surface and "alloy" the Cu with Sn atoms, to make "bronze".
- The islands continually move into "unalloyed" regions and leave tiny bronze particles in their wake.
- Eventually, the islands disappear.

13

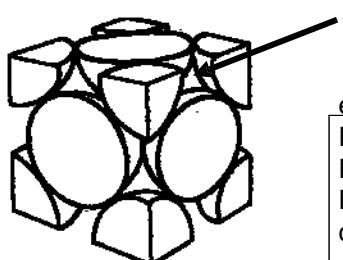

## Solubility for solid solutions

### B. Interstitial solutions:

Large difference in atomic radii is usually required.

Most metals have close packing with relatively large APF.  
(e.g.  $\text{APF}_{\text{FCC}} = \text{APF}_{\text{HCP}} = 0.74$ . that means 74% of the space is filled!)

Only small atoms will fit into these small interstitial sites without requiring high energies.

e.g.  $\text{CinFe}$ :

$$R_{\text{C}} = 0.071 \text{ nm}$$

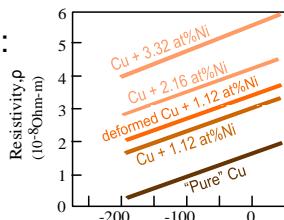

$$R_{\text{Fe}} = 0.124 \text{ nm}$$

Even with this large difference max. conc. is only ~2%  $\text{CinFe}$

14

## Effects of Composition in Solid Solutions

**Electrical:**

**Mechanical:** Strengthening  
(a major purpose of making alloys)

and many more effects...

Composition can change  
Phases/Structure which in turn  
determine properties!

## Composition Specification

Definition: Amount of impurity (B) and host (A) in the system.

Two descriptions:

- Weight%

$$C_B = \frac{\text{mass of B}}{\text{total mass}} \times 100$$

- Atom%

$$C'_B = \frac{\# \text{ atoms of B}}{\text{total # atoms}} \times 100$$

- Conversion between wt% and at% in an A-B alloy:

$$C_B = \frac{C'_B AB}{C'_A AA + C'_B AB} \times 100$$

$$C'_B = \frac{C_B / AB}{C_A / AA + C_B / AB}$$

- Basis for conversion:

$$\begin{array}{l} \text{mass of B} = \text{moles of B} \\ \text{mass of A} = \text{moles of A} \end{array}$$

$$\begin{array}{l} x A_B \xrightarrow{\text{atomic weight of B}} \\ x A_A \xrightarrow{\text{atomic weight of A}} \end{array}$$

16

## Exampleproblem:conversion

- Determine the composition in at% of an alloy with 80wt% Al and 20wt%Cu

$$A_{Al} = 26.98 \text{ g/mol}$$

$$A_{Cu} = 63.55 \text{ g/mol}$$

17

## Averagealloydensity

$$\rho_{avg} = \frac{\text{total mass}}{\text{total volume}} = \frac{m_A + m_B}{V_A + V_B}$$

$$\text{With } V_A = \frac{m_A}{\rho_A} \text{ and } V_B = \frac{m_B}{\rho_B}$$

$$\rho_{avg} = \frac{m_A + m_B}{m_A/\rho_A + m_B/\rho_B}$$

In terms of wt% and at%:

$$\rho_{avg} = \frac{100 \cdot C / \rho}{C / \rho}$$

$$\rho_{avg} = \frac{C_A + C_A}{C_A / \rho + C_A / \rho}$$

A A A A      B B B B

# Imperfections in ionic solids

Recall point defects in solids....

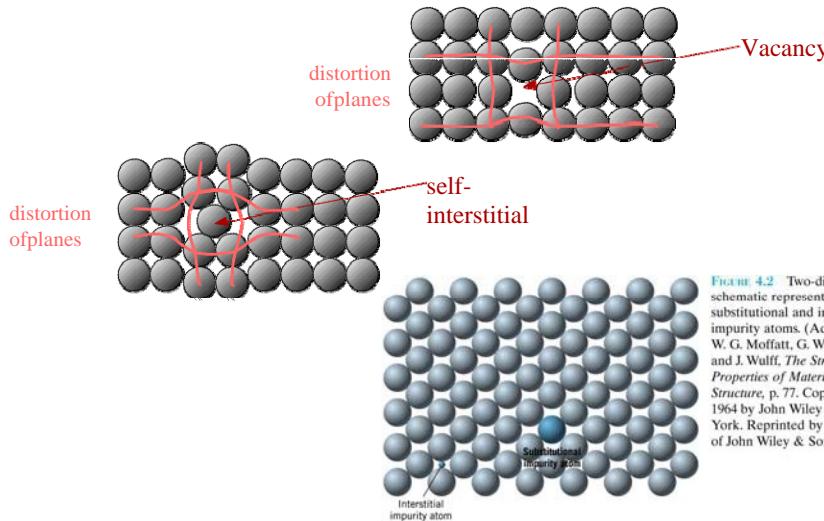

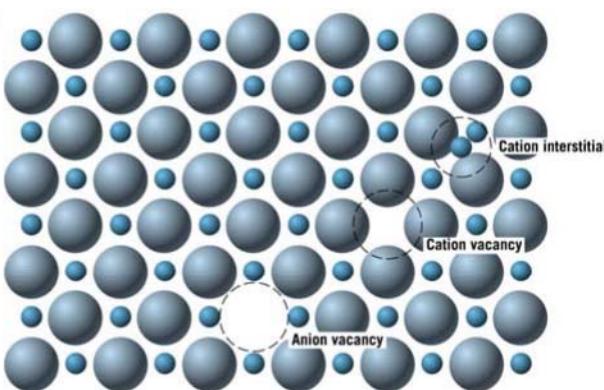

FIGURE 4.2 Two-dimensional schematic representations of substitutional and interstitial impurity atoms. (Adapted from W. G. Moffatt, G. W. Pearsall, and J. Wulff, *The Structure and Properties of Materials*, Vol. I, *Structure*, p. 77. Copyright © 1964 by John Wiley & Sons, New York. Reprinted by permission of John Wiley & Sons, Inc.)

80

# Imperfections in ionic solids

Point defects also possible in ionic solids. But...?

FIGURE 12.20 Schematic representations of cation and anion vacancies and a cation interstitial. (From W. G. Moffatt, G. W. Pearsall, and J. Wulff, *The Structure and Properties of Materials*, Vol. 1, *Structure*, p. 78. Copyright © 1964 by John Wiley & Sons, New York. Reprinted by permission of John Wiley & Sons, Inc.)

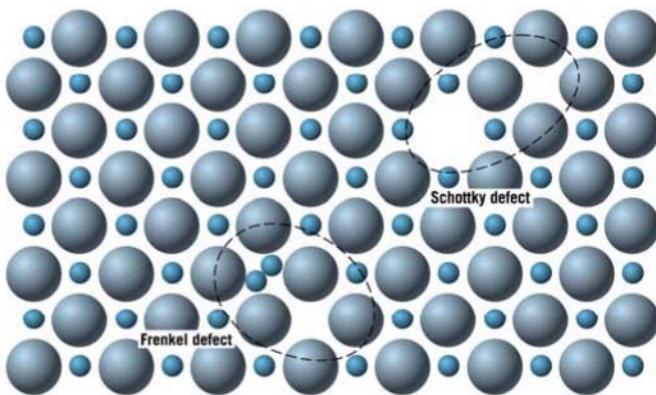

Charge neutrality needs to be met!

20

# Imperfections in ionic solids

**FIGURE 12.21**  
Schematic diagram showing Frenkel and Schottky defects in ionic solids. (From W. G. Moffatt, G. W. Pearsall, and J. Wulff, *The Structure and Properties of Materials*, Vol. 1, *Structure*, p. 78. Copyright © 1964 by John Wiley & Sons, New York. Reprinted by permission of John Wiley & Sons, Inc.)

Can we have a Frenkel defect of anions?

21

## Example problem

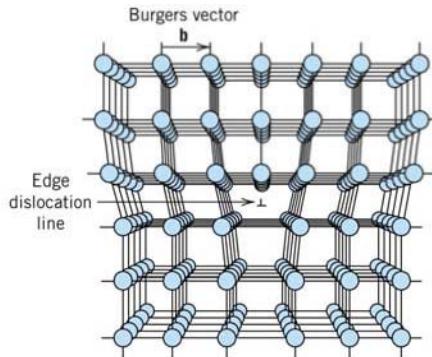

1. When a  $\text{Ca}^{2+}$  ion is substituted for a  $\text{Na}^+$  ion in a  $\text{NaCl}$  crystal, what point defects are possible and how many of these defects exist for every  $\text{Ca}^{2+}$  ion?
2. What point defects are possible for  $\text{MgO}$  as an impurity in  $\text{Al}_2\text{O}_3$  and how many  $\text{Mg}^{2+}$  ions must be added to form each of these defects?

22

# Linear Defects: edge dislocation

**Dislocations:** Linear defects around which atoms are misaligned

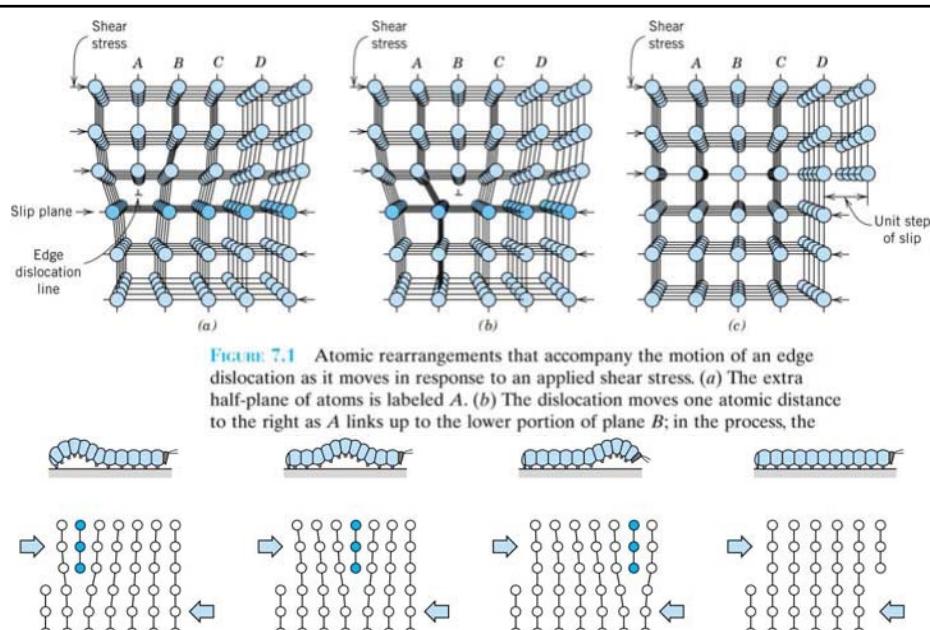

1. **Edge dislocation:** Linear defect that centers around a line that is defined along the end of an extra plane of atoms

**FIGURE 4.3** The atom positions around an edge dislocation; extra half-plane of atoms shown in perspective. (Adapted from A. G. Guy, *Essentials of Materials Science*, McGraw-Hill Book Company, New York, 1976, p. 153.)

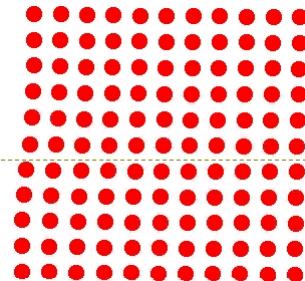

Denoted by  $\text{L}$  or  $\text{T}$   
Points to the extra plane of atoms

23

24

# Edgedislocation

Atomic view of edge dislocation motion from left to right as a crystal is sheared.

(Courtesy P.M. Anderson)

Note that the edge dislocations causes slip between crystal planes when they move leading to **plastic** (permanent) **deformation**.

25

## Linear Defects: Screw dislocation

2. **Screw dislocation**: shifted by one atomic distance

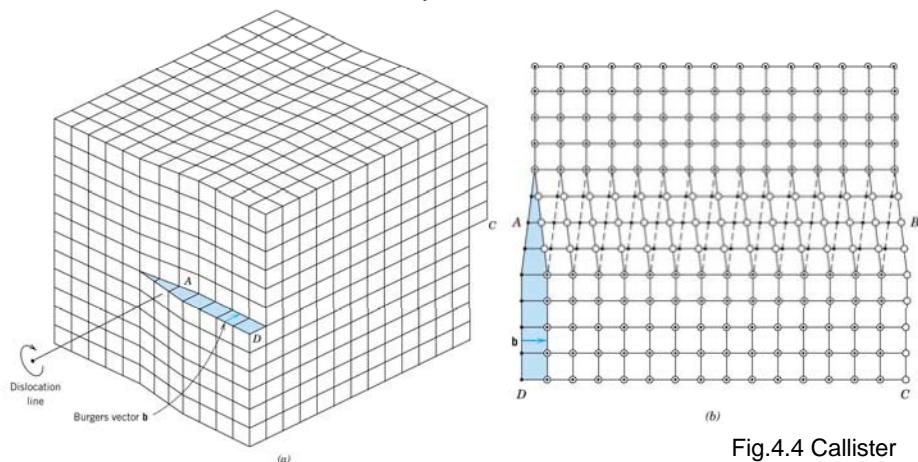

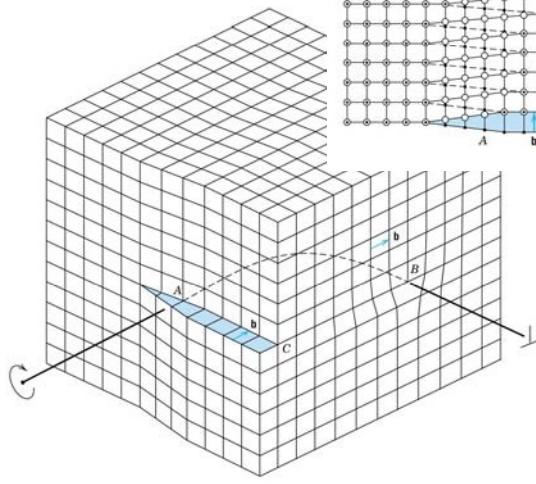

Fig.4.4 Callister

26

## Mixed edge/screw dislocation

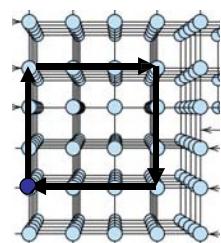

**FIGURE 4.5**  
 (a) Schematic representation of a dislocation that has edge, screw, and mixed character. (b) Top view, where open circles denote atom positions above the slip plane. Solid circles, atom positions below. At point A, the dislocation is pure screw, while at point B, it is pure edge. For regions in between where there is curvature in the dislocation line, the character is mixed edge and screw. (Figure b from W. T. Read, Jr., *Dislocations in Crystals*, McGraw-Hill Book Company, New York, 1953.)

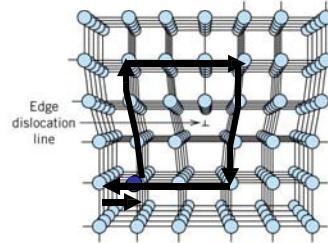

Topview

27

## Burgers Vector

Perfect lattice  
Back at the same atom

With an edge dislocation  
Need to go back an atomic spacing to end at the same atom.

**Burgers vector:** the magnitude and direction of the lattice distortion associated with dislocations

28

## Example:Burgers vector

- FindtheBurgersvectorforaBCCcrystal.

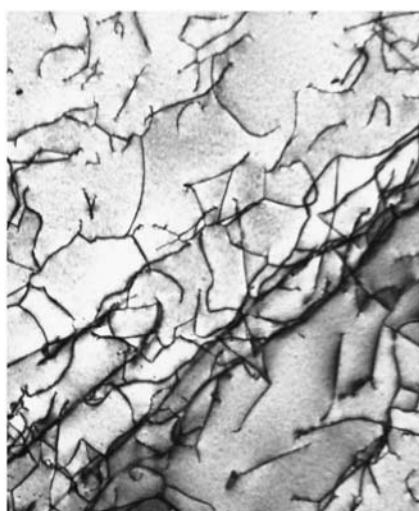

Note:BurgersvectorsforBCCandFCCcan  
beexpressedas

$$\frac{a}{2} [hkl]$$

Latticeparameter                            Millerindex

Calculate the magnitude of Burgers vector for  $\alpha$ -Fe (BCC) given  
that  $R_{\text{Fe}} = 0.1241 \text{ nm}$ . Compare to the atomic spacing of  $2R_{\text{Fe}}$ .

## Observing dislocations

**FIGURE 4.6** A transmission electron micrograph of a titanium alloy in which the dark lines are dislocations. 51,450 $\times$ . (Courtesy of M. R. Plichta, Michigan Technological University.)

# Planar Defects

## Primary defect types:

### Surfaces & Interfaces

- Places where reactions occur and materials mix

### Grain Boundaries

- Lattices (and so bonds) do not match up

### Twins

- Plane shear to change material shape

### Stacking Faults

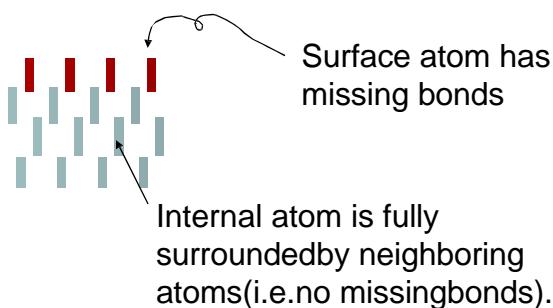

- Errors in stacking (e.g.: ABCABCABACBACBABCABC)

31

# External surface

- surface atoms are in higher energy states than internal atoms.

## Why?

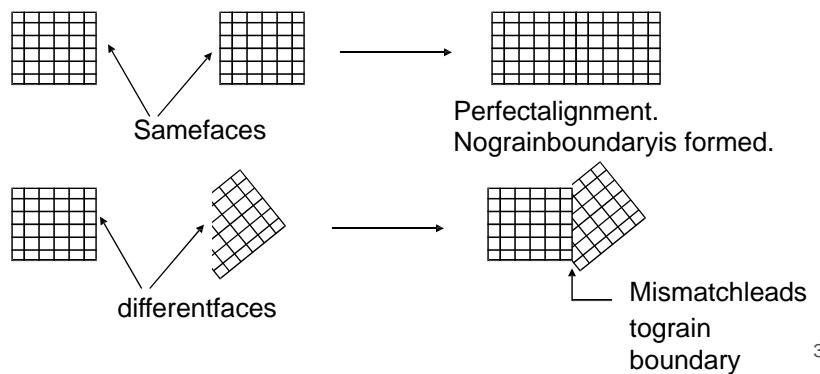

32

# Grain Boundaries

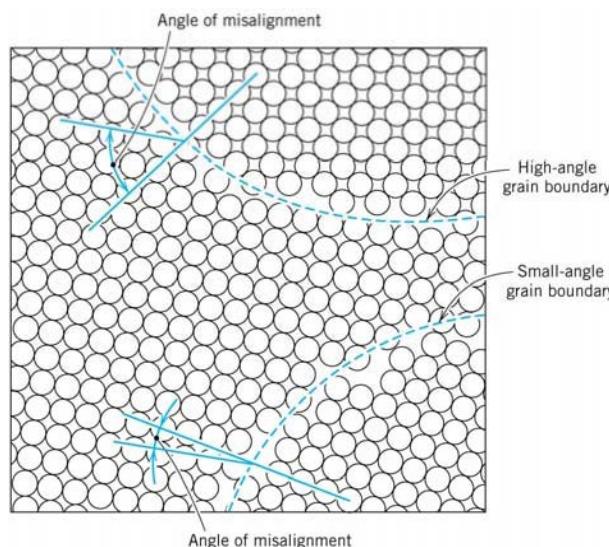

- 2D defects that separate small grains (crystals having different crystallographic orientations within a polycrystalline material)

**single crystal:** periodic arrangement of atoms is perfect and extends throughout the entire crystal.

• **polycrystalline:** composed of many small crystals (grains).

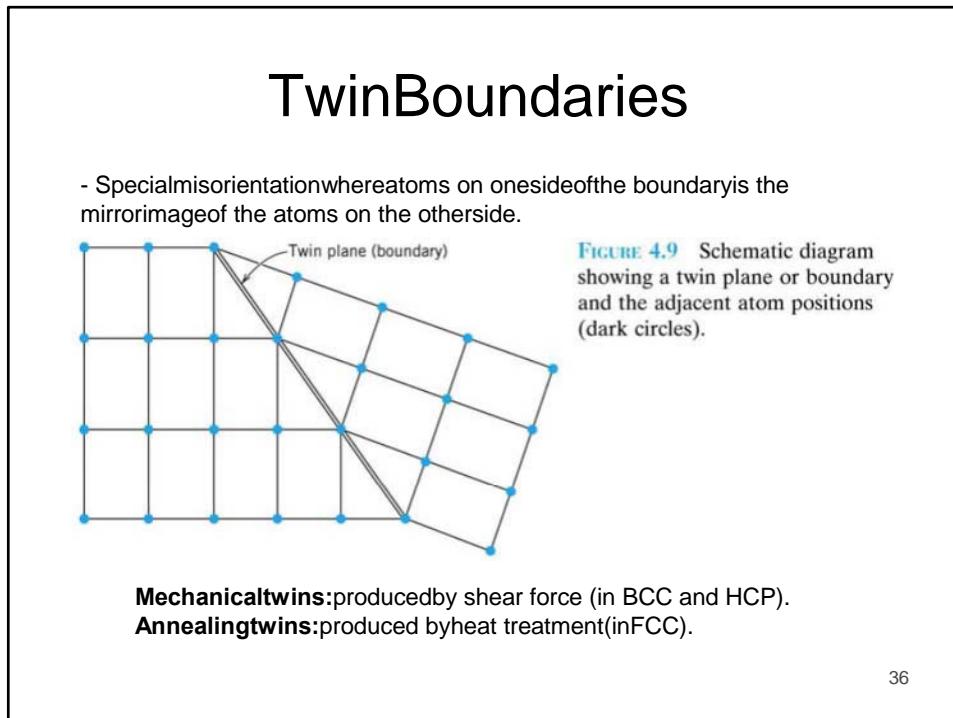

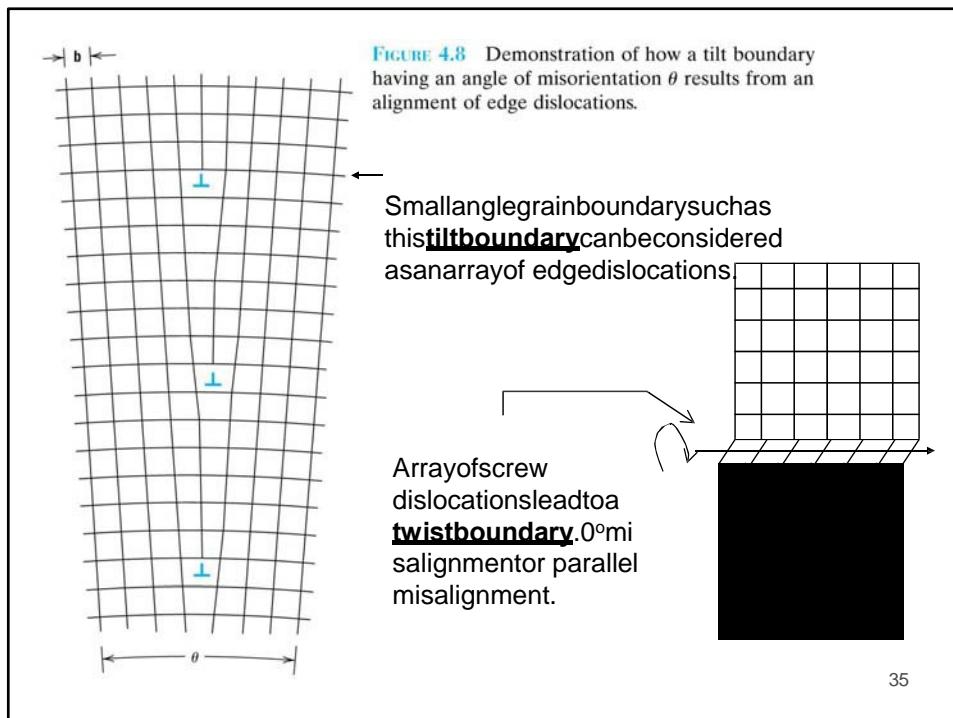

33

**FIGURE 4.7** Schematic diagram showing small- and high-angle grain boundaries and the adjacent atom positions.

Depending on which planes are brought together, the angle of misalignment will vary.

34

# Effects of grain boundaries

## Changes in mechanical properties

- Boundaries are good places for fracture to occur
- Boundaries interrupt the movement of dislocations

## Changes in electrical properties

- Good places to scatter electrons or inhibit their movement

## Sites for atom diffusion

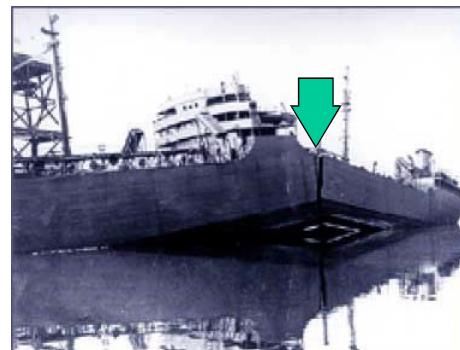

- Diffusing atoms move more easily in the boundaries
- Some atoms like to sit in the boundaries (weaken them)
- Materials can "creep" which means even metals at high temperatures can flow like liquids by diffusion, often through grain boundaries.

37

# Materials Embrittlement

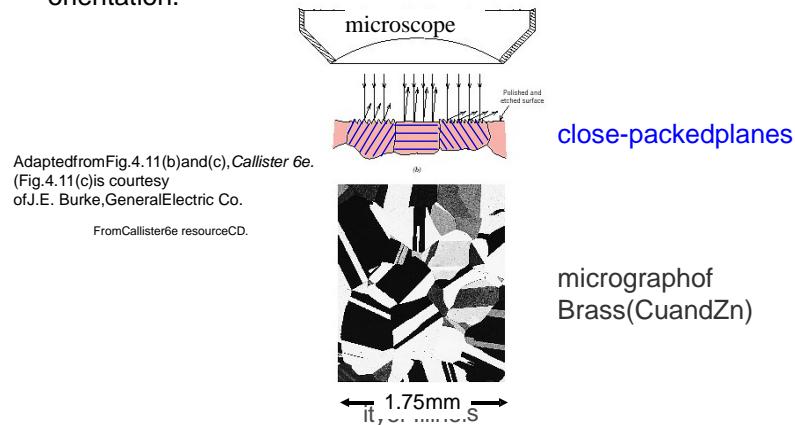

Oops...

A World War I liberty ship which broke in half due to poor welds. The major problem was sulfur impurities in the iron of the weld which caused weak grain boundaries.

## Observing grain boundaries: Optical microscopy

- Useful up to 2000X magnification.
- Polishing removes surface features (e.g., scratches)
- Etching changes reflectance, depending on crystal orientation.

39

## Stacking faults

Any time the stacking sequence of atoms makes a difference an error in stacking of atoms can change the properties of the material

Example: stacking faults can convert FCC to HCP structures. Materials of these two structures often contain such faults and many have altered properties as a result.

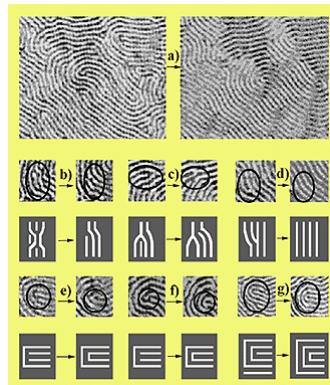

Stacking faults look almost exactly like twins in the electron microscope.

40

## Imperfections in polymers

- Some are similar to metals and ceramics: e.g. **interstitials** and **vacancies**.
- **Chain ends** can be considered as imperfections since they are different than the repeating units (e.g. initiator attached at end).
- **Amorphous regions** between crystalline regions.
- **Copolymers**:

Defect diffusion in block-copolymers

41

## Concepts to remember

- **Point defects**: vacancies, self-interstitials, impurities.
- **Solid solutions**: interstitial, substitutional, solubility, and alloy composition and densities.
- **Dislocations**: edge, screw, dislocation motion, and Burgers vector.
- **Grain boundaries and related**: tilt and twist boundaries, surfaces, interfaces, twins, stacking faults, and optical microscopy.
- **Imperfections have very important consequences on the properties of materials.**

42
