Database Management System

Lecture 1 Fundamental Database Concepts

CONTENTS

- Basics of DBMS
- Purpose of DBMS
- Applications of DBMS
- Views of Data
- Instances and Schema
- Data Models
- Database Languages
- Responsibility of Database Administrator

Database Management System (DBMS)

- DBMS contains information about a particular enterprise
 - Collection of interrelated data
 - Set of programs to access the data
 - An environment that is both convenient and efficient to use

DBMS is a software (i.e. programs along with environment) which manages interrelated data about a particular enterprise.

Database Management System (DBMS)

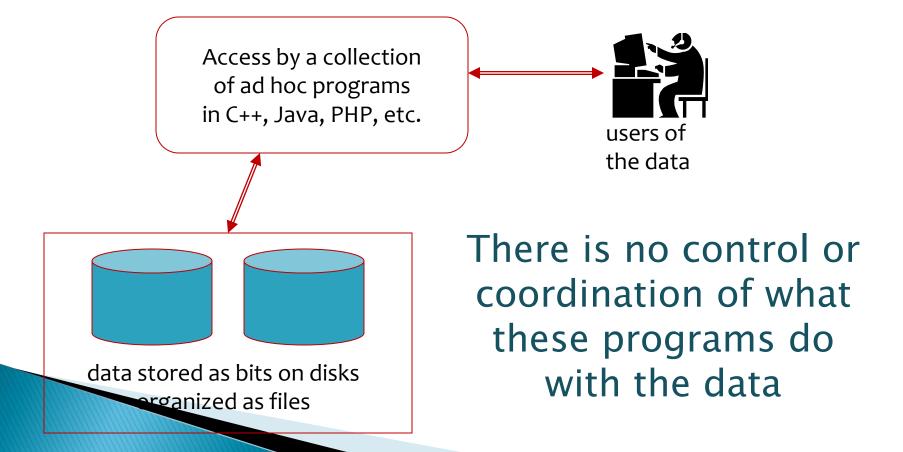

- Data is facts/ information.
- A database is any collection of data.
- A DBMS is a software system designed to maintain a database.
- A <u>Database Management System (DBMS)</u> is a software package designed to store and manage databases.
- We use a DBMS when
 - there is a large amount of data
 - security and integrity of the data are important
 - many users access the data concurrently

Basic Definitions

- Database: A collection of related data.
- Data: Known facts that can be recorded and have an implicit meaning.
- Mini-world: Some part of the real world about which data is stored in a database. For example, student grades and transcripts at a university.
- Database Management System (DBMS): A software package/ system to facilitate the creation and maintenance of a computerized database.
- Database System: The DBMS software together with the data itself. Sometimes, the applications are also included.

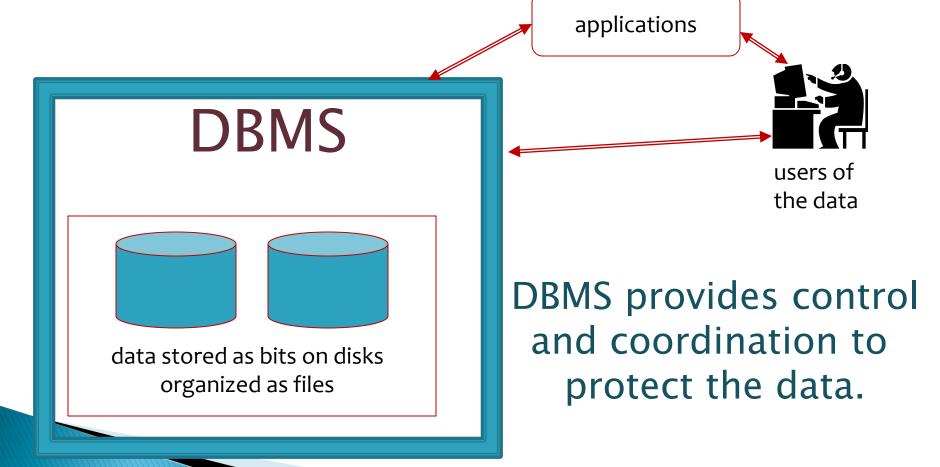

Why Use a DBMS?

Without a DBMS, we'd have:

Why Use a DBMS?

With a DBMS, we have:

Purpose of Database Systems

- In the early days, database applications were built directly on top of file systems
- Drawbacks of using file systems to store data:
 - Data redundancy and inconsistency
 - Multiple file formats, duplication of information in different files
 - Difficulty in accessing data
 - Need to write a new program to carry out each new task
 - Data isolation multiple files and formats
 - Integrity problems
 - Integrity constraints (e.g. account balance > 0) become "buried" in program code rather than being stated explicitly
 - Hard to add new constraints or change existing ones

Purpose of Database Systems

- Drawbacks of using file systems (cont.)
 - Atomicity of updates
 - Failures may leave database in an inconsistent state with partial updates carried out
 - Example: Transfer of funds from one account to another should either complete or not happen at all
 - Concurrent access by multiple users
 - Concurrent accessed needed for performance
 - Uncontrolled concurrent accesses can lead to inconsistencies
 - Example: Two people reading a balance and updating it at the same time
 - Security problems
 - Hard to provide user access to some, but not all, data
- Database systems offer solutions to all the above problems

Typical DBMS Functionality

- Define a database: in terms of data types, structures and constraints
- Construct or Load the Database on a secondary storage medium
- Manipulating the database : querying, generating reports, insertions, deletions and modifications to its content
- Concurrent Processing and Sharing by a set of users and programs – yet, keeping all data valid and consistent

Typical DBMS Functionality

Other features:

- Protection or Security measures to prevent unauthorized access
- "Active" processing to take internal actions on data
- Presentation and Visualization of data

Main Characteristics of the Database Approach

- Self-describing nature of a database system: A DBMS catalog stores the description of the database. The description is called meta-data). This allows the DBMS software to work with different databases.
- Insulation between programs and data: Called program-data independence. Allows changing data storage structures and operations without having to change the DBMS access programs.
- Data Abstraction: A data model is used to hide storage details and present the users with a conceptual view of the database.

Main Characteristics of the Database Approach

- Support of multiple views of the data: Each user may see a different view of the database, which describes only the data of interest to that user.
- Sharing of data and multiuser transaction processing: allowing a set of concurrent users to retrieve and to update the database. Concurrency control within the DBMS guarantees that each **transaction** is correctly executed or completely aborted. OLTP (Online Transaction Processing) is a major part of database applications.

Applications of DBMS

- > Banking: all transactions
- > Airlines: reservations, schedules
- > Universities: registration, grades
- > Sales: customers, products, purchases
- Online retailers: order tracking, customized recommendations
- Manufacturing: production, inventory, orders, supply chain
- > Human resources: employee records, salaries, tax deductions

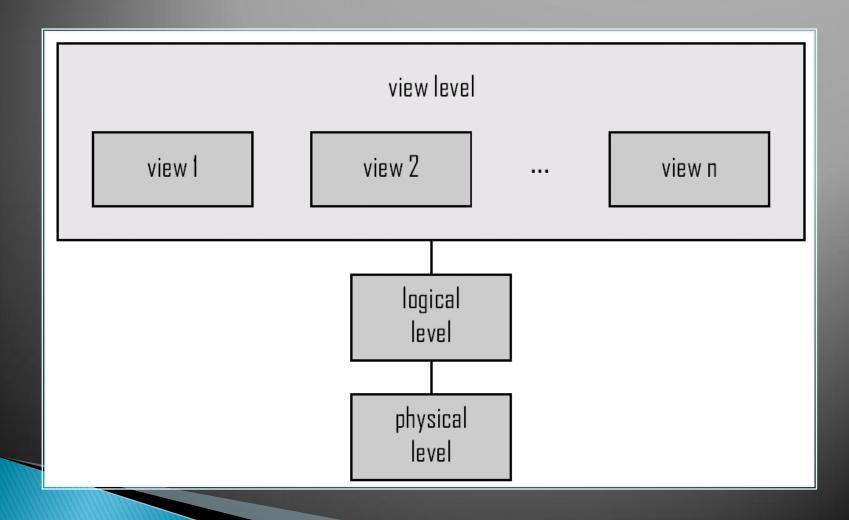

Levels of Abstraction

- Physical level: describes how a record (e.g., customer) is stored.
- Logical level: describes data stored in database, and the relationships among the data.

View level: application programs hide details of data types.
Views can also hide information (such as an employee's salary) for security purposes.

View of Data

An architecture for a database system

Instances and Schemas

- Similar to types and variables in programming languages
- Schema the logical structure of the database
 Structural Description of the type of facts held in a database.
 - Example: The database consists of information about a set of customers and accounts and the relationship between them)
 - Analogous to type information of a variable in a program
 - Physical schema: database design at the physical level
 - Logical schema: database design at the logical level
- Instance the actual content of the database at a particular point in time
 - Analogous to the value of a variable
- Physical Data Independence the ability to modify the physical schema without changing the logical schema
 - Applications depend on the logical schema
 - In general, the interfaces between the various levels and components should be well defined so that changes in some parts do not seriously influence others.

Data Models

- A collection of tools for describing
 - Data
 - Data relationships
 - Data semantics
 - Data constraints

There are a number of different ways of organizing a schema, i.e. of modeling a database structure, these ways are known as **Data Models**.

Types of Data Models

- Relational model
- Entity-Relationship data model (mainly for database design)
- Object-based data models (Object-oriented and Object-relational)
- Semistructured data model (XML)
- Other older models:
 - Network model
 - Hierarchical model

Data Manipulation Language (DML)

- Language for accessing and manipulating the data organized by the appropriate data model
 - DML also known as query language
- Two classes of languages
 - Procedural user specifies what data is required and how to get those data (PL/SQL)
 - Declarative (nonprocedural) user specifies what data is required without specifying how to get those data (SQL)
- SQL is the most widely used query language

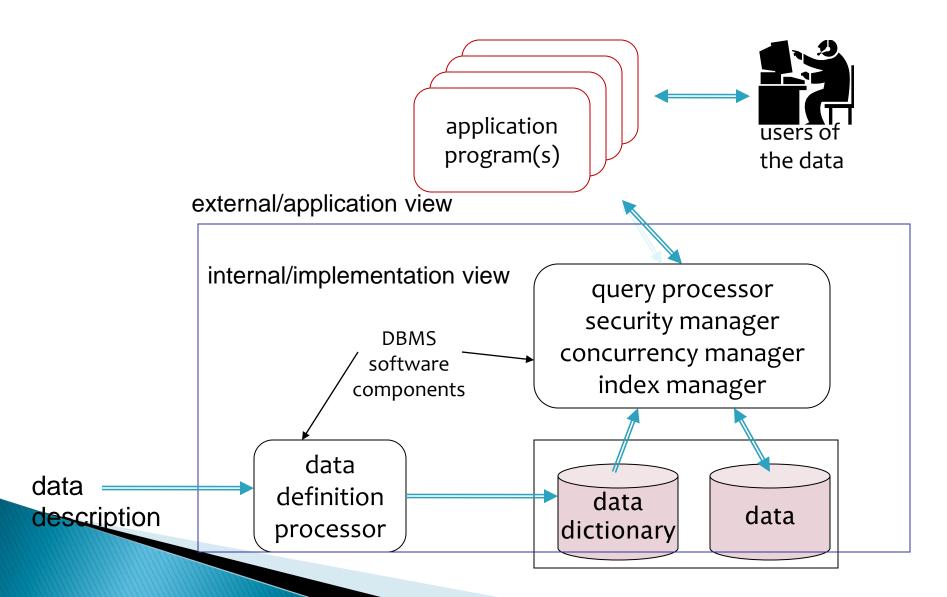

Data Definition Language (DDL)

Specification notation for defining the database schema
 Example: create table account (

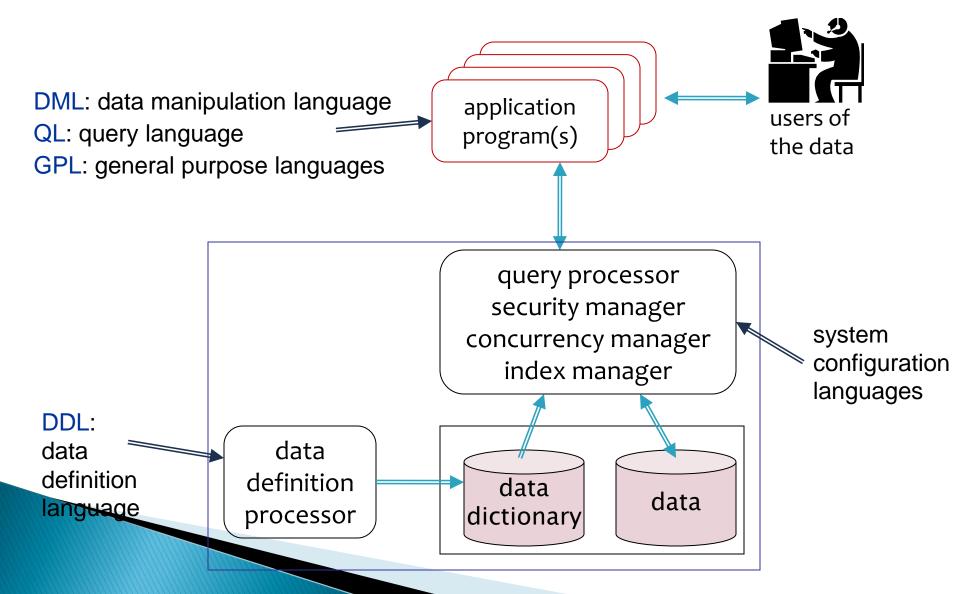

```
account_number char(10),
branch_name char(10),
balance integer)
```

- DDL compiler generates a set of tables stored in a data dictionary
- Data dictionary contains metadata (i.e., data about data)
 - Database schema
 - Data storage and definition language
 - Specifies the storage structure and access methods used
 - Integrity constraints
 - Domain constraints
 - Referential integrity (e.g. branch_name must correspond to a valid branch in the branch table)
 - **Authorization**

DBMS Structure

DBMS Languages

Database Users

Users are differentiated by the way they expect to interact with the system

- Application programmers interact with system through DML calls
- Sophisticated users form requests in a database query language
- Specialized users write specialized database applications that do not fit into the traditional data processing framework
- Naïve users invoke one of the permanent application programs that have been written previously
 - Examples, people accessing database over the web, bank tellers, clerical staff

Database Administrator

- Coordinates all the activities of the database system
 - has a good understanding of the enterprise's information resources and needs.
- Database administrator's duties include:
 - Storage structure and access method definition
 - Schema and physical organization modification
 - Granting users authority to access the database
 - Backing up data
 - Monitoring performance and responding to changes
 - Database tuning

Database Architecture

The architecture of a database systems is greatly influenced by the underlying computer system on which the database is running:

- Centralized
- Client-server
- Parallel (multiple processors and disks)
- Distributed
