

# LOCAL AREA NETWORK

Protocols for Multiple Access Control

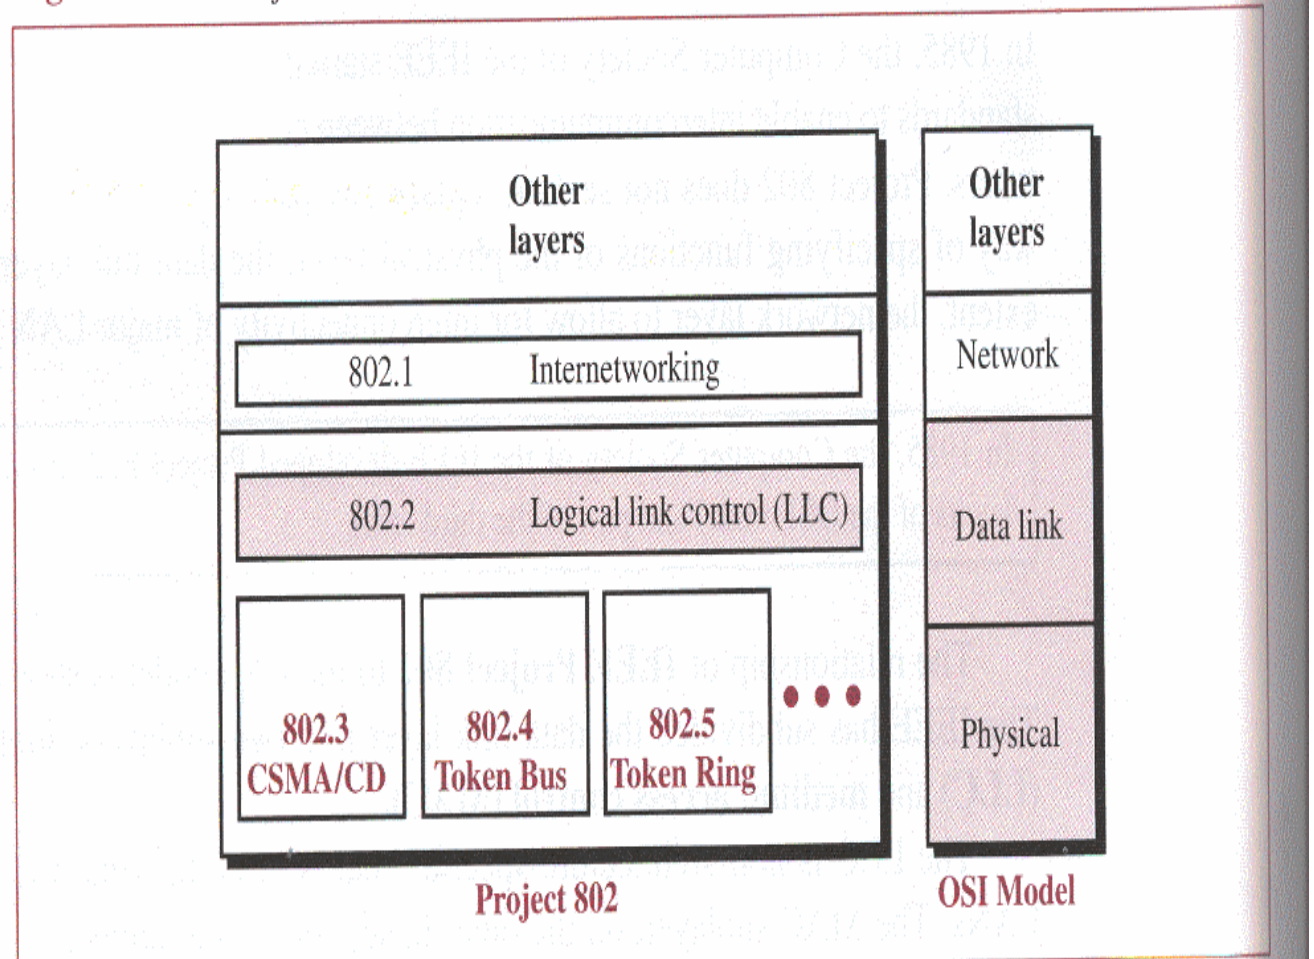

# Introduction

- Data links in networks can be of two types:
  - Dedicated *point to point*
  - Shared/ Multiple Access
- So, Data Link Layer is divided into two layers:
  - LLC: Logical Link Control
  - MAC: Multiple Access Control

Data link layer

# Taxonomy of multiple-access protocols discussed in this chapter

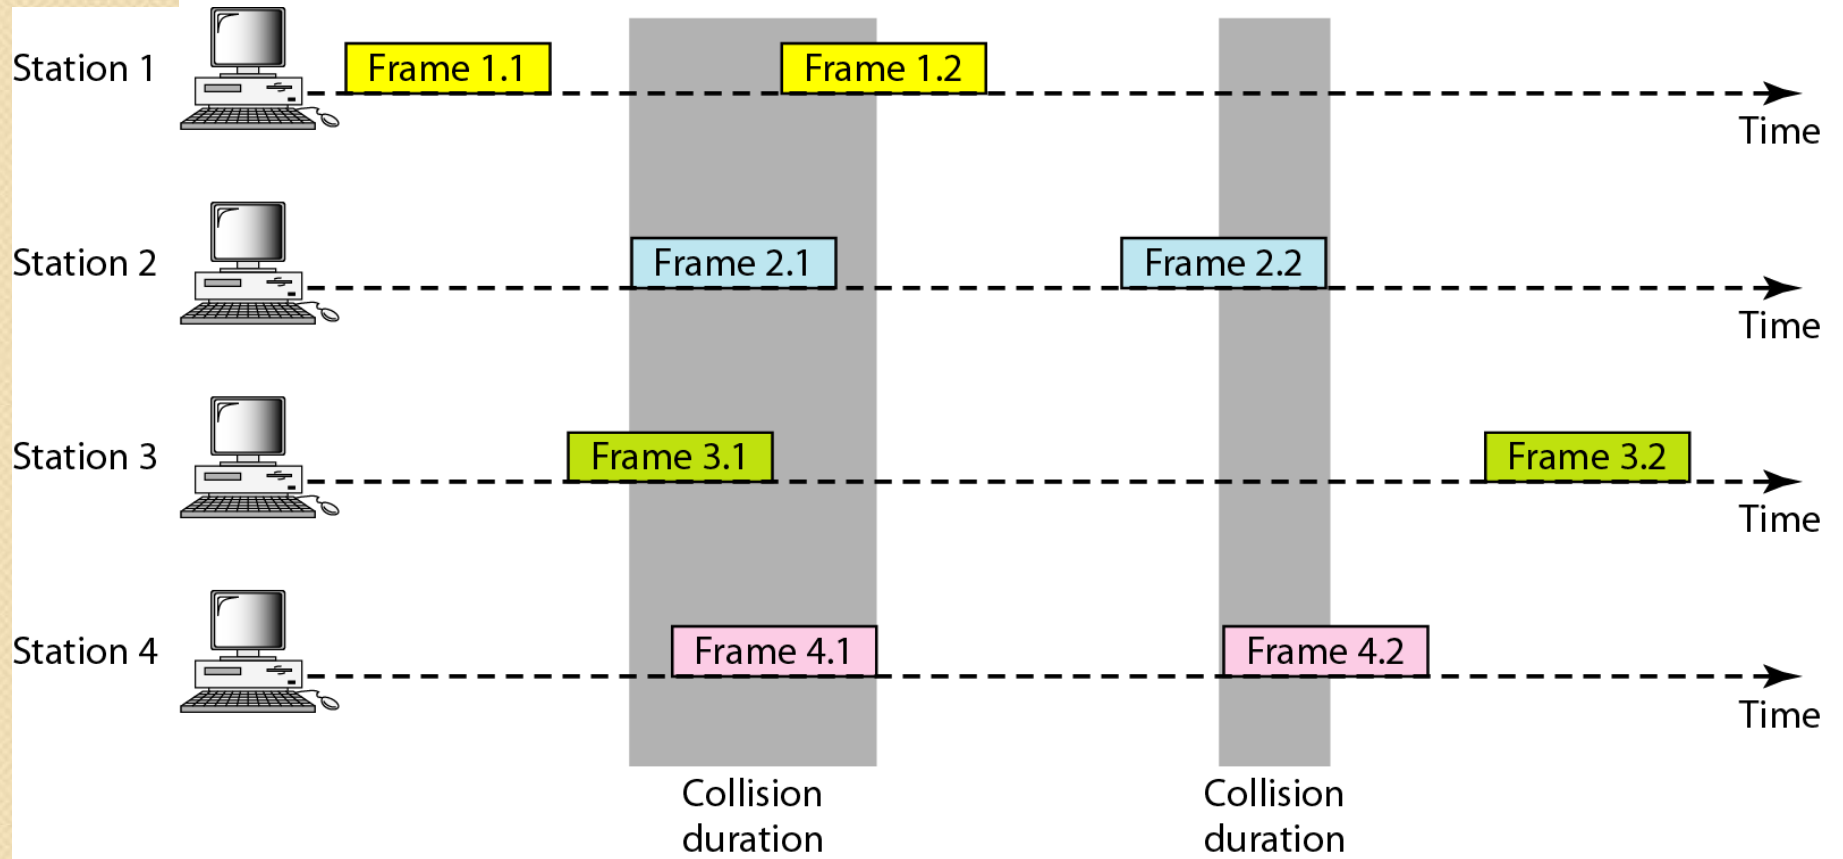

# RANDOM ACCESS

In **random access** or **contention** methods, no station is superior to another station and none is assigned the control over another. No station permits, or does not permit, another station to send. At each instance, a station that has data to send uses a procedure defined by the protocol to make a decision on whether or not to send. Different random access methods are:

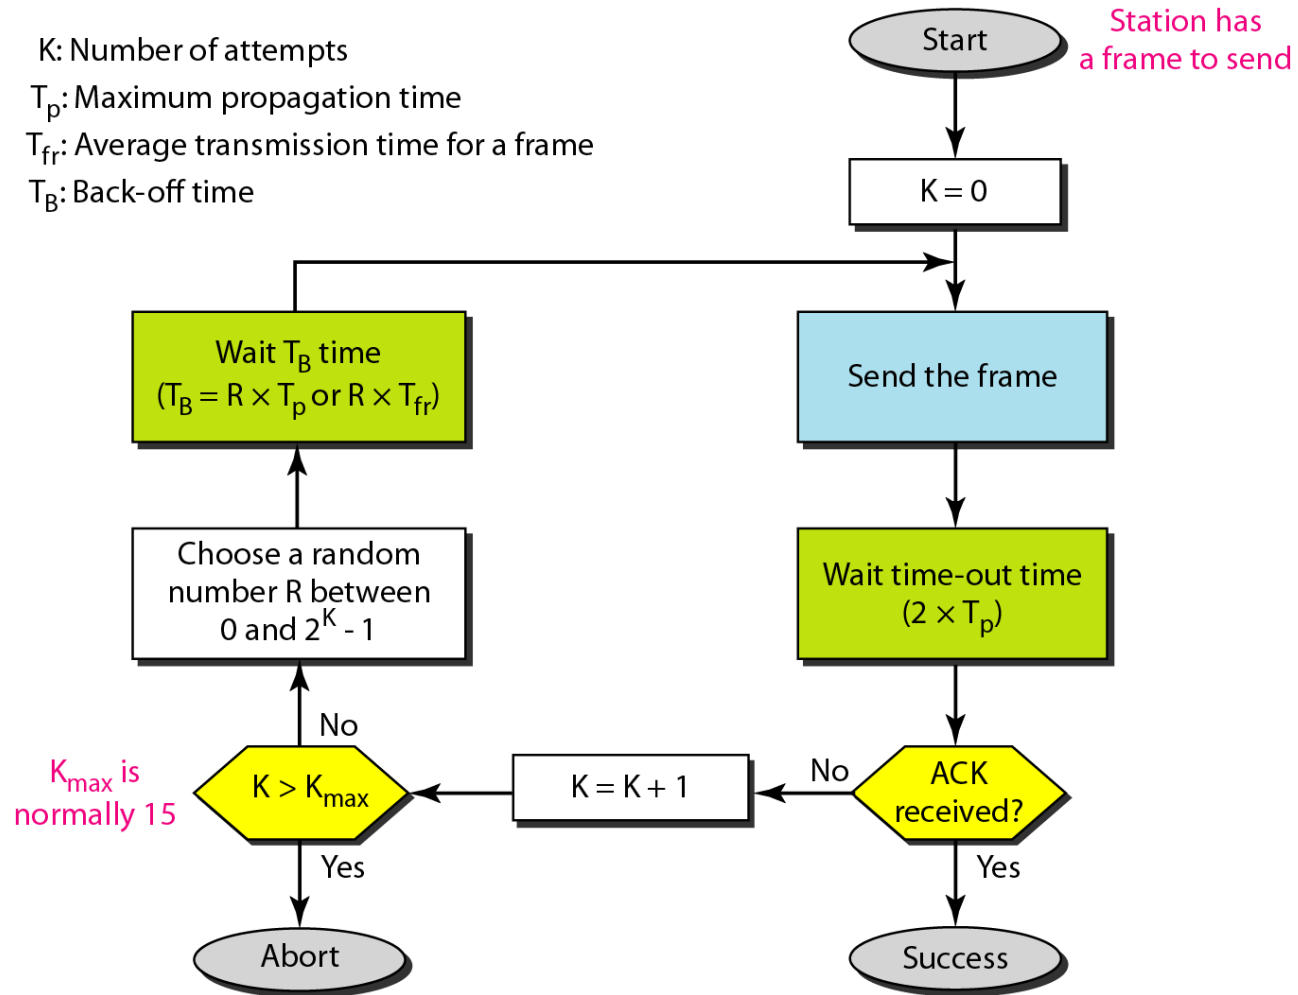

- ALOHA
- Carrier Sense Multiple Access
- Carrier Sense Multiple Access with Collision Detection
- Carrier Sense Multiple Access with Collision Avoidance

# Frames in a pure ALOHA network

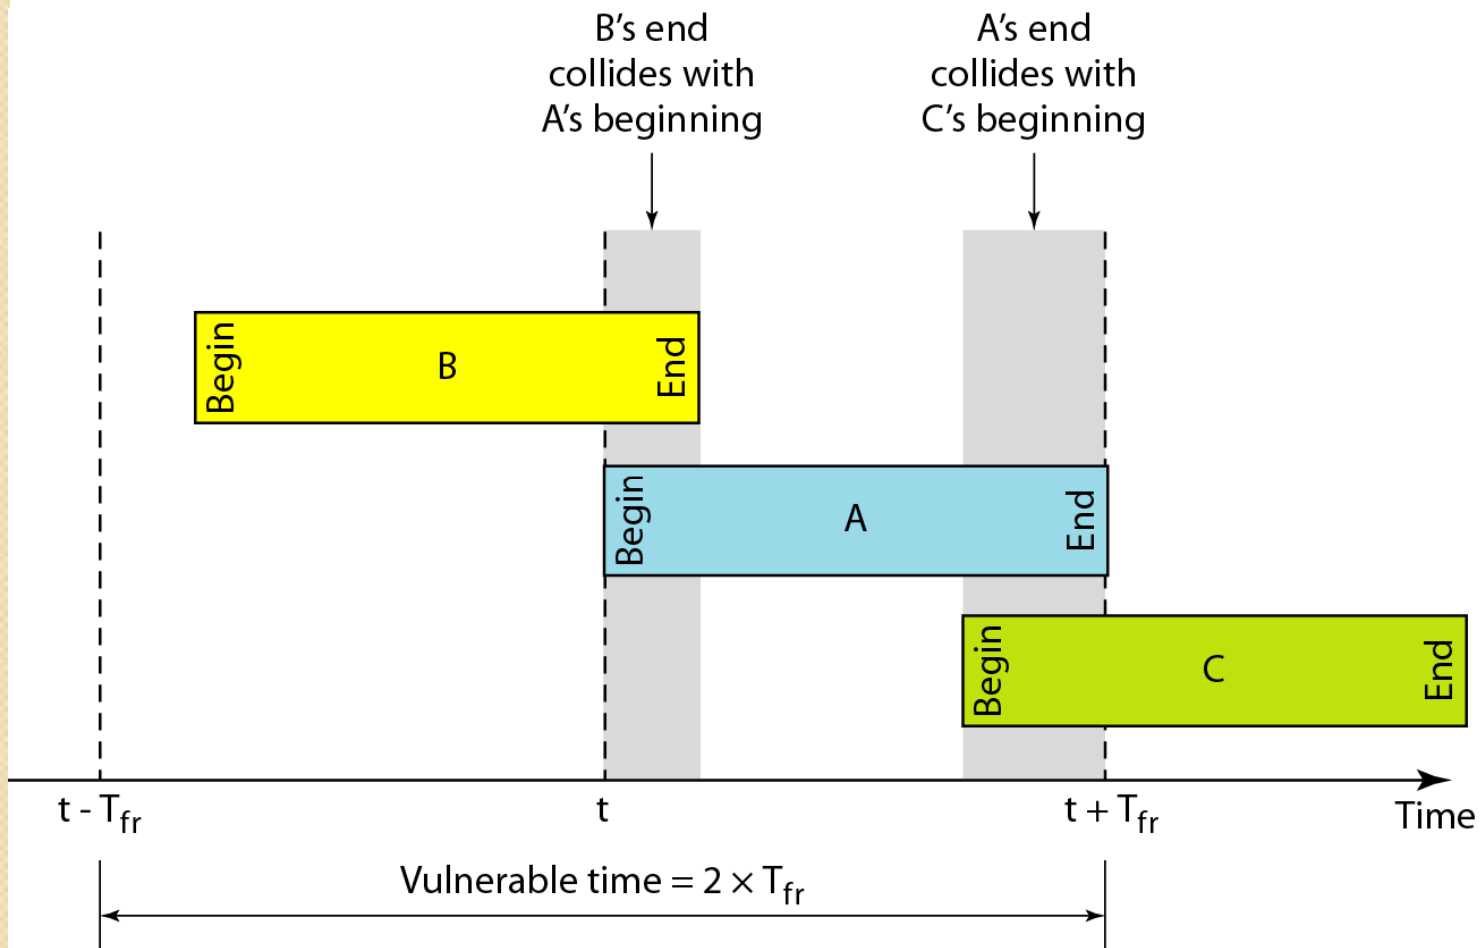

# Procedure for pure ALOHA protocol

K: Number of attempts  
 $T_p$ : Maximum propagation time  
 $T_{fr}$ : Average transmission time for a frame  
 $T_B$ : Back-off time

# Vulnerable time for pure ALOHA protocol

## Example

A pure ALOHA network transmits 200-bit frames on a shared channel of 200 kbps. What is the requirement to make this frame collision-free?

### Solution

Average frame transmission time  $T_{fr}$  is 200 bits/200 kbps or 1 ms. The vulnerable time is  $2 \times 1 \text{ ms} = 2 \text{ ms}$ . This means no station should send later than 1 ms before this station starts transmission and no station should start sending during the one 1-ms period that this station is sending.

Note

The throughput for pure ALOHA is

$$S = G \times e^{-2G}$$

G=Average number of frames generated by the system during one frame transmission time

The maximum throughput

$$S_{\max} = 0.184 \text{ when } G = (1/2).$$

## Example

A pure ALOHA network transmits 200-bit frames on a shared channel of 200 kbps. What is the throughput if the system (all stations together) produces

- a. 1000 frames per second
- b. 500 frames per second
- c. 250 frames per second.

### Solution

The frame transmission time is  $200/200$  kbps or 1 ms.

- a. If the system creates 1000 frames per second, this is 1 frame per millisecond. The load is 1. In this case  $S = G \times e^{-2G}$  or  $S = 0.135$  (13.5 percent). This means that the throughput is  $1000 \times 0.135 = 135$  frames. Only 135 frames out of 1000 will probably survive.

## Example (continued)

- b. If the system creates 500 frames per second, this is (1/2) frame per millisecond. The load is (1/2). In this case  $S = G \times e^{-2G}$  or  $S = 0.184$  (18.4 percent). This means that the throughput is  $500 \times 0.184 = 92$  and that only 92 frames out of 500 will probably survive. Note that this is the maximum throughput case, percentagewise.
- c. If the system creates 250 frames per second, this is (1/4) frame per millisecond. The load is (1/4). In this case  $S = G \times e^{-2G}$  or  $S = 0.152$  (15.2 percent). This means that the throughput is  $250 \times 0.152 = 38$ . Only 38 frames out of 250 will probably survive.

# Frames in a slotted ALOHA network

Note

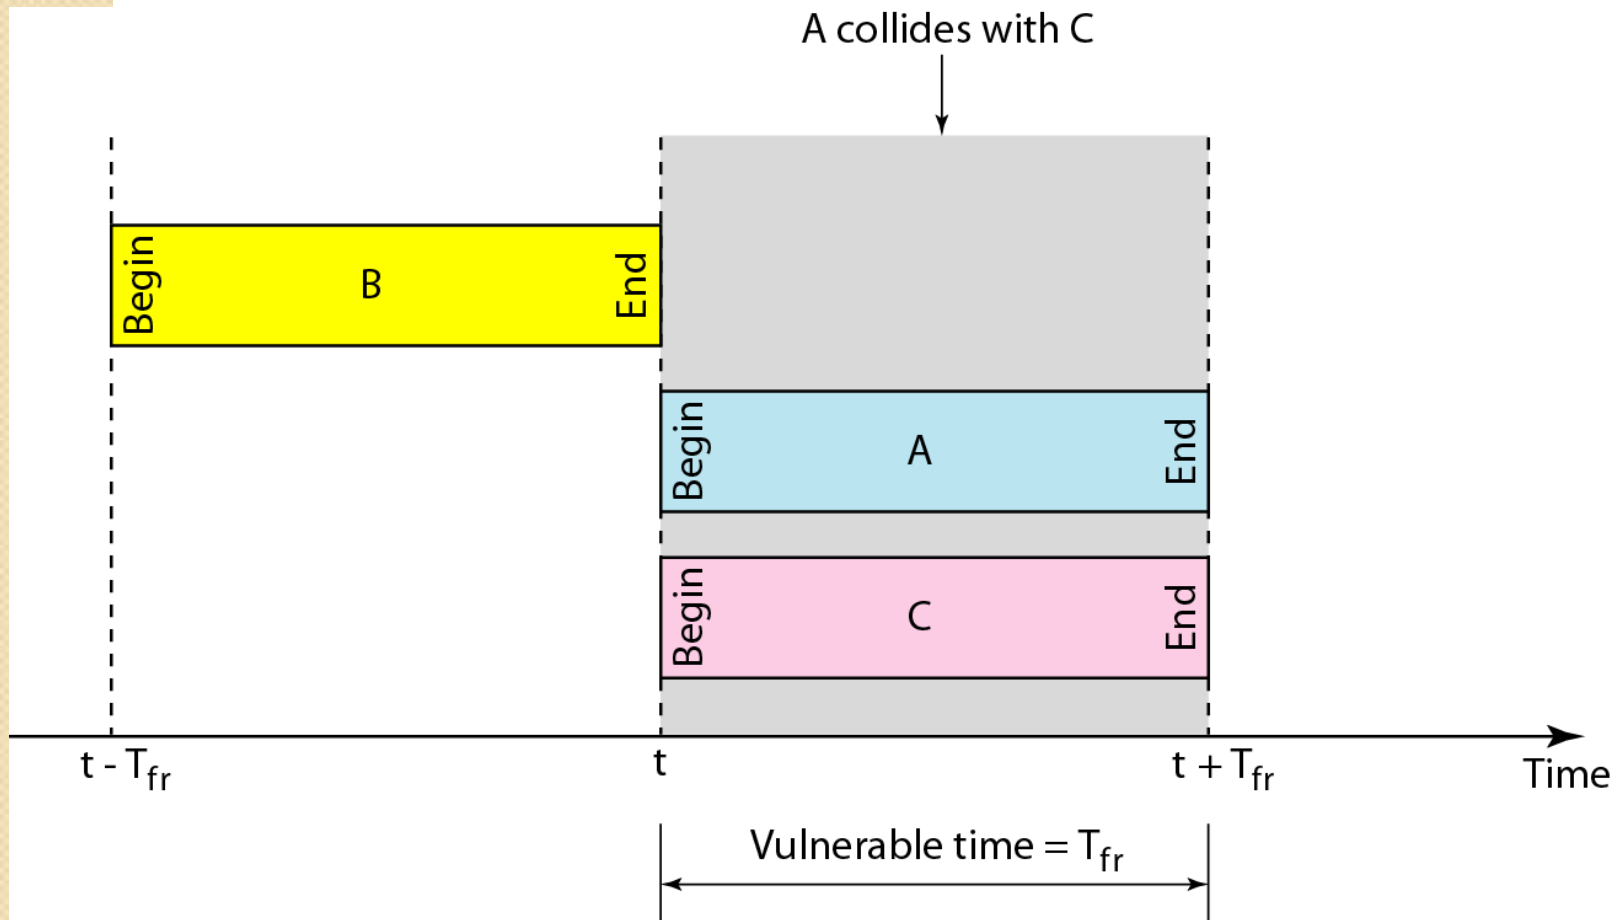

The throughput for slotted ALOHA is

$$S = G \times e^{-G} .$$

The maximum throughput

$$S_{\max} = 0.368 \text{ when } G = 1 .$$

# Vulnerable time for slotted ALOHA protocol

## Example

A slotted ALOHA network transmits 200-bit frames on a shared channel of 200 kbps. What is the throughput if the system (all stations together) produces

- a. 1000 frames per second
- b. 500 frames per second
- c. 250 frames per second.

### Solution

The frame transmission time is  $200/200$  kbps or 1 ms.

- a. If the system creates 1000 frames per second, this is 1 frame per millisecond. The load is 1. In this case  $S = G \times e^{-G}$  or  $S = 0.368$  (36.8 percent). This means that the throughput is  $1000 \times 0.368 = 368$  frames. Only 368 frames out of 1000 will probably survive.

## Example (continued)

- b. If the system creates 500 frames per second, this is (1/2) frame per millisecond. The load is (1/2). In this case  $S = G \times e^{-G}$  or  $S = 0.303$  (30.3 percent). This means that the throughput is  $500 \times 0.303 = 151$ . Only 151 frames out of 500 will probably survive.
- c. If the system creates 250 frames per second, this is (1/4) frame per millisecond. The load is (1/4). In this case  $S = G \times e^{-G}$  or  $S = 0.195$  (19.5 percent). This means that the throughput is  $250 \times 0.195 = 49$ . Only 49 frames out of 250 will probably survive.

# Space/time model of the collision in CSMA

# Vulnerable time in CSMA

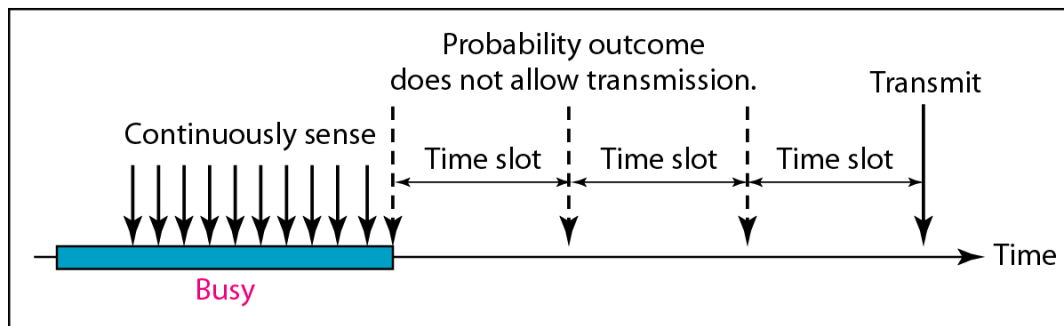

# Behavior of three persistence methods

a. 1-persistent

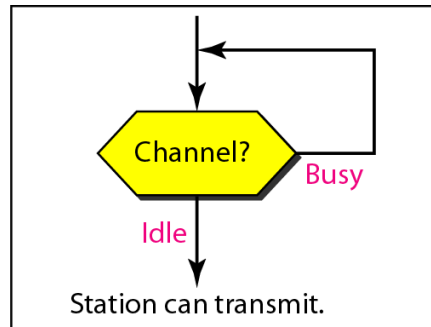

b. Nonpersistent

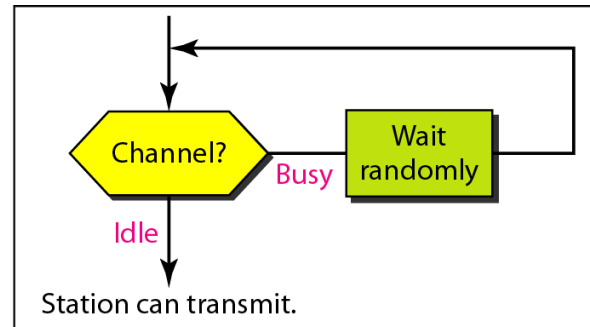

c. p-persistent

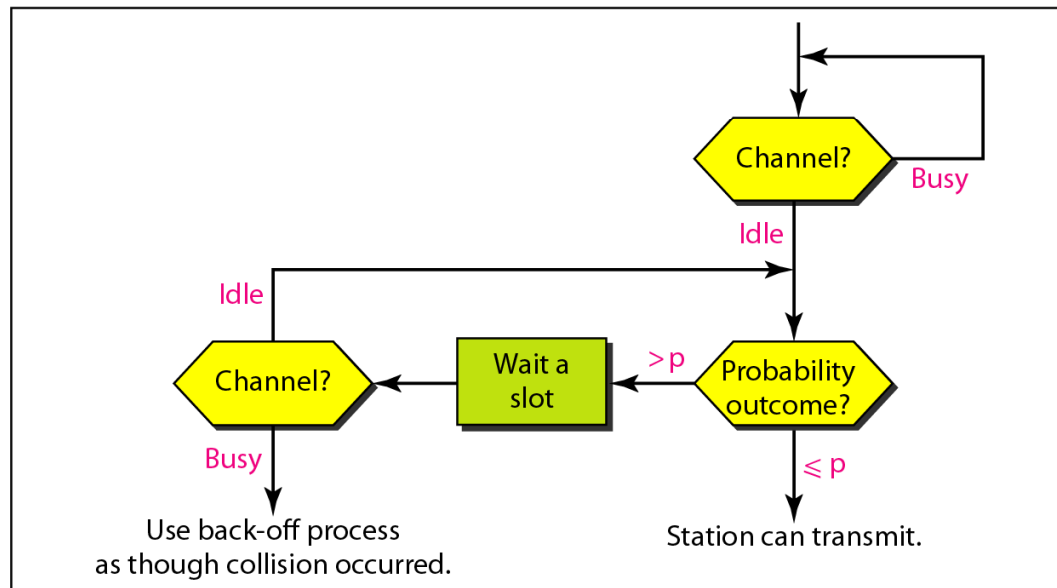

# Flow diagram for three persistence methods

a. 1-persistent

b. Nonpersistent

c. p-persistent

# Application

- Multiple Access Protocols are used in case of shared media/ shared channels
- These protocols are applicable in wireless communications

# Scope of Research

- Protocol Support for 3G and 4G networks
- MAC algorithms for mobile networks
- MAC algorithms for wireless adhoc networks

# Assignment

- Why performance of slotted Aloha is better than Pure Aloha?
